Upon entering SMM, the processor switches to a new address space. Because paging is disabled upon entering SMM, this initial address space maps all memory accesses to the low 4 GBytes of the processor's physical address space. The SMI handler's critical code and data reside in a memory region referred to as system-management RAM (SMRAM). The processor uses a pre-defined region within SMRAM to save the processor's pre-SMI context. SMRAM can also be used to store system management information (such as the system configuration and specific information about powered-down devices) and OEM-specific information.

The default SMRAM size is 64 KBytes beginning at a base physical address in physical memory called the SMBASE (see Figure 32-1). The SMBASE default value following a hardware reset is 30000H. The processor looks for the first instruction of the SMI handler at the address [SMBASE + 8000H]. It stores the processor's state in the area from [SMBASE + FE00H] to [SMBASE + FFFFH]. See Section 32.4.1 for a description of the mapping of the state save area.

The system logic is minimally required to decode the physical address range for the SMRAM from [SMBASE + 8000H] to [SMBASE + FFFFH]. A larger area can be decoded if needed. The size of this SMRAM can be between 32 KBytes and 4 GBytes.

The location of the SMRAM can be changed by changing the SMBASE value (see Section 32.11). It should be noted that all processors in a multiple-processor system are initialized with the same SMBASE value (30000H). Initialization software must sequentially place each processor in SMM and change its SMBASE so that it does not overlap those of other processors.

The actual physical location of the SMRAM can be in system memory or in a separate RAM memory. The processor generates an SMI acknowledge transaction (P6 family processors) or asserts the SMIACK# pin (Pentium and Intel486 processors) when the processor receives an SMI (see Section 32.3.1).

System logic can use the SMI acknowledge transaction or the assertion of the SMIACK# pin to decode accesses to the SMRAM and redirect them (if desired) to specific SMRAM memory. If a separate RAM memory is used for SMRAM, system logic should provide a programmable method of mapping the SMRAM into system memory space when the processor is not in SMM. This mechanism will enable start-up procedures to initialize the SMRAM space (that is, load the SMI handler) before executing the SMI handler during SMM.

### 32.4.1 SMRAM State Save Map

When an IA-32 processor that does not support Intel 64 architecture initially enters SMM, it writes its state to the state save area of the SMRAM. The state save area begins at [SMBASE + 8000H + 7FFFH] and extends down to [SMBASE + 8000H + 7E00H]. Table 32-1 shows the state save map. The offset in column 1 is relative to the SMBASE value plus 8000H. Reserved spaces should not be used by software.

Some of the registers in the SMRAM state save area (marked YES in column 3) may be read and changed by the SMI handler, with the changed values restored to the processor registers by the RSM instruction. Some register images are read-only, and must not be modified (modifying these registers will result in unpredictable behavior). An SMI handler should not rely on any values stored in an area that is marked as reserved.

Figure 32-1. SMRAM Usage

Table 32-1. SMRAM State Save Map

| Offset<br>(Added to SMBASE + 8000H) | Register                                   | Writable? |
|-------------------------------------|--------------------------------------------|-----------|
| 7FFCH                               | CR0                                        | No        |
| 7FF8H                               | CR3                                        | No        |
| 7FF4H                               | EFLAGS                                     | Yes       |
| 7FF0H                               | EIP                                        | Yes       |
| 7FECH                               | EDI                                        | Yes       |
| 7FE8H                               | ESI                                        | Yes       |
| 7FE4H                               | EBP                                        | Yes       |
| 7FE0H                               | ESP                                        | Yes       |
| 7FDCH                               | EBX                                        | Yes       |
| 7FD8H                               | EDX                                        | Yes       |
| 7FD4H                               | ECX                                        | Yes       |
| 7FD0H                               | EAX                                        | Yes       |
| 7FCCH                               | DR6                                        | No        |
| 7FC8H                               | DR7                                        | No        |
| 7FC4H                               | TR <sup>1</sup>                            | No        |
| 7FC0H                               | Reserved                                   | No        |
| 7FBCH                               | GS <sup>1</sup>                            | No        |
| 7FB8H                               | FS <sup>1</sup>                            | No        |
| 7FB4H                               | DS <sup>1</sup>                            | No        |
| 7FB0H                               | SS <sup>1</sup>                            | No        |
| 7FACH                               | CS <sup>1</sup>                            | No        |
| 7FA8H                               | ES <sup>1</sup>                            | No        |
| 7FA4H                               | I/O State Field, see Section 32.7          | No        |
| 7FA0H                               | I/O Memory Address Field, see Section 32.7 | No        |
| 7F9FH-7F03H                         | Reserved                                   | No        |
| 7F02H                               | Auto HALT Restart Field (Word)             | Yes       |
| 7F00H                               | I/O Instruction Restart Field (Word)       | Yes       |
| 7EFCH                               | SMM Revision Identifier Field (Doubleword) | No        |
| 7EF8H                               | SMBASE Field (Doubleword)                  | Yes       |
| 7EF7H - 7E00H                       | Reserved                                   | No        |

**NOTE:**

1. The two most significant bytes are reserved.

The following registers are saved (but not readable) and restored upon exiting SMM:

- Control register CR4. (This register is cleared to all 0s when entering SMM).
- The hidden segment descriptor information stored in segment registers CS, DS, ES, FS, GS, and SS.

If an SMI request is issued for the purpose of powering down the processor, the values of all reserved locations in the SMM state save must be saved to nonvolatile memory.

The following state is not automatically saved and restored following an SMI and the RSM instruction, respectively:

## SYSTEM MANAGEMENT MODE

- Debug registers DR0 through DR3.
- The x87 FPU registers.
- The MTRRs.
- Control register CR2.
- The model-specific registers (for the P6 family and Pentium processors) or test registers TR3 through TR7 (for the Pentium and Intel486 processors).
- The state of the trap controller.
- The machine-check architecture registers.
- The APIC internal interrupt state (ISR, IRR, etc.).
- The microcode update state.

If an SMI is used to power down the processor, a power-on reset will be required before returning to SMM, which will reset much of this state back to its default values. So an SMI handler that is going to trigger power down should first read these registers listed above directly, and save them (along with the rest of RAM) to nonvolatile storage. After the power-on reset, the continuation of the SMI handler should restore these values, along with the rest of the system's state. Anytime the SMI handler changes these registers in the processor, it must also save and restore them.

### NOTES

A small subset of the MSRs (such as, the time-stamp counter and performance-monitoring counters) are not arbitrarily writable and therefore cannot be saved and restored. SMM-based power-down and restoration should only be performed with operating systems that do not use or rely on the values of these registers.

Operating system developers should be aware of this fact and ensure that their operating-system assisted power-down and restoration software is immune to unexpected changes in these register values.

#### 32.4.1.1 SMRAM State Save Map and Intel 64 Architecture

When the processor initially enters SMM, it writes its state to the state save area of the SMRAM. The state save area on an Intel 64 processor at [SMBASE + 8000H + 7FFFH] and extends to [SMBASE + 8000H + 7C00H].

Support for Intel 64 architecture is reported by CPUID.80000001:EDX[29] = 1. The layout of the SMRAM state save map is shown in Table 32-3.

Additionally, the SMRAM state save map shown in Table 32-3 also applies to processors with the following CPUID signatures listed in Table 32-2, irrespective of the value in CPUID.80000001:EDX[29].

**Table 32-2. Processor Signatures and 64-bit SMRAM State Save Map Format**

| DisplayFamily_DisplayModel | Processor Families/Processor Number Series                                                                                                                         |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 06_17H                     | Intel Xeon Processor 5200, 5400 series, Intel Core 2 Quad processor Q9xxx, Intel Core 2 Duo processors E8000, T9000,                                               |
| 06_0FH                     | Intel Xeon Processor 3000, 3200, 5100, 5300, 7300 series, Intel Core 2 Quad, Intel Core 2 Extreme, Intel Core 2 Duo processors, Intel Pentium dual-core processors |

**NOTE:**

1. The two most significant bytes are reserved.

### 32.4.2 SMRAM Caching

An IA-32 processor does not automatically write back and invalidate its caches before entering SMM or before exiting SMM. Because of this behavior, care must be taken in the placement of the SMRAM in system memory and in the caching of the SMRAM to prevent cache incoherence when switching back and forth between SMM and protected mode operation. Any of the following three methods of locating the SMRAM in system memory will guarantee cache coherency.

- Place the SMRAM in a dedicated section of system memory that the operating system and applications are prevented from accessing. Here, the SMRAM can be designated as cacheable (WB, WT, or WC) for optimum processor performance, without risking cache incoherence when entering or exiting SMM.
- Place the SMRAM in a section of memory that overlaps an area used by the operating system (such as the video memory), but designate the SMRAM as uncacheable (UC). This method prevents cache access when in SMM to maintain cache coherency, but the use of uncacheable memory reduces the performance of SMM code.
- Place the SMRAM in a section of system memory that overlaps an area used by the operating system and/or application code, but explicitly flush (write back and invalidate) the caches upon entering and exiting SMM mode. This method maintains cache coherency, but incurs the overhead of two complete cache flushes.

For Pentium 4, Intel Xeon, and P6 family processors, a combination of the first two methods of locating the SMRAM is recommended. Here the SMRAM is split between an overlapping and a dedicated region of memory. Upon entering SMM, the SMRAM space that is accessed overlaps video memory (typically located in low memory). This SMRAM section is designated as UC memory. The initial SMM code then jumps to a second SMRAM section that is

located in a dedicated region of system memory (typically in high memory). This SMRAM section can be cached for optimum processor performance.

For systems that explicitly flush the caches upon entering SMM (the third method described above), the cache flush can be accomplished by asserting the FLUSH# pin at the same time as the request to enter SMM (generally initiated by asserting the SMI# pin). The priorities of the FLUSH# and SMI# pins are such that the FLUSH# is serviced first. To guarantee this behavior, the processor requires that the following constraints on the interaction of FLUSH# and SMI# be met. In a system where the FLUSH# and SMI# pins are synchronous and the set up and hold times are met, then the FLUSH# and SMI# pins may be asserted in the same clock. In asynchronous systems, the FLUSH# pin must be asserted at least one clock before the SMI# pin to guarantee that the FLUSH# pin is serviced first.

Upon leaving SMM (for systems that explicitly flush the caches), the WBINVD instruction should be executed prior to leaving SMM to flush the caches.

## NOTES

In systems based on the Pentium processor that use the FLUSH# pin to write back and invalidate cache contents before entering SMM, the processor will prefetch at least one cache line in between when the Flush Acknowledge cycle is run and the subsequent recognition of SMI# and the assertion of SMIACK#.

It is the obligation of the system to ensure that these lines are not cached by returning KEN# inactive to the Pentium processor.

### 32.4.2.1 System Management Range Registers (SMRR)

SMI handler code and data stored by SMM code resides in SMRAM. The SMRR interface is an enhancement in Intel 64 architecture to limit cacheable reference of addresses in SMRAM to code running in SMM. The SMRR interface can be configured only by code running in SMM. Details of SMRR is described in Section 12.11.2.4.

## 32.5 SMI HANDLER EXECUTION ENVIRONMENT

Section 32.5.1 describes the initial execution environment for an SMI handler. An SMI handler may re-configure its execution environment to other supported operating modes. Section 32.5.2 discusses modifications an SMI handler can make to its execution environment. Section 32.5.3 discusses Control-flow Enforcement Technology (CET) interactions in the environment.

### 32.5.1 Initial SMM Execution Environment

After saving the current context of the processor, the processor initializes its core registers to the values shown in Table 32-4. Upon entering SMM, the PE and PG flags in control register CR0 are cleared, which places the processor in an environment similar to real-address mode. The differences between the SMM execution environment and the real-address mode execution environment are as follows:

- The addressable address space ranges from 0 to FFFFFFFF (4 GBytes).
- The normal 64-KByte segment limit for real-address mode is increased to 4 GBytes.
- The default operand and address sizes are set to 16 bits, which restricts the addressable SMRAM address space to the 1-MByte real-address mode limit for native real-address-mode code. However, operand-size and address-size override prefixes can be used to access the address space beyond the 1-MByte.

**Table 32-4. Processor Register Initialization in SMM**

| Register                  | Contents                                      |
|---------------------------|-----------------------------------------------|
| General-purpose registers | Undefined                                     |
| EFLAGS                    | 00000002H                                     |
| EIP                       | 00008000H                                     |
| CS selector               | SMM Base shifted right 4 bits (default 3000H) |

**Table 32-4. Processor Register Initialization in SMM**

|                              |                                                      |
|------------------------------|------------------------------------------------------|
| CS base                      | SMM Base (default 30000H)                            |
| DS, ES, FS, GS, SS Selectors | 0000H                                                |
| DS, ES, FS, GS, SS Bases     | 00000000H                                            |
| DS, ES, FS, GS, SS Limits    | 0FFFFFFFH                                            |
| CR0                          | PE, EM, TS, and PG flags set to 0; others unmodified |
| CR4                          | Cleared to zero                                      |
| DR6                          | Undefined                                            |
| DR7                          | 00000400H                                            |

- Near jumps and calls can be made to anywhere in the 4-GByte address space if a 32-bit operand-size override prefix is used. Due to the real-address-mode style of base-address formation, a far call or jump cannot transfer control to a segment with a base address of more than 20 bits (1 MByte). However, since the segment limit in SMM is 4 GBytes, offsets into a segment that go beyond the 1-MByte limit are allowed when using 32-bit operand-size override prefixes. Any program control transfer that does not have a 32-bit operand-size override prefix truncates the EIP value to the 16 low-order bits.
- Data and the stack can be located anywhere in the 4-GByte address space, but can be accessed only with a 32-bit address-size override if they are located above 1 MByte. As with the code segment, the base address for a data or stack segment cannot be more than 20 bits.

The value in segment register CS is automatically set to the default of 30000H for the SMBASE shifted 4 bits to the right; that is, 3000H. The EIP register is set to 8000H. When the EIP value is added to shifted CS value (the SMBASE), the resulting linear address points to the first instruction of the SMI handler.

The other segment registers (DS, SS, ES, FS, and GS) are cleared to 0 and their segment limits are set to 4 GBytes. In this state, the SMRAM address space may be treated as a single flat 4-GByte linear address space. If a segment register is loaded with a 16-bit value, that value is then shifted left by 4 bits and loaded into the segment base (hidden part of the segment register). The limits and attributes are not modified.

Maskable hardware interrupts, exceptions, NMI interrupts, SMI interrupts, A20M interrupts, single-step traps, breakpoint traps, and INIT operations are inhibited when the processor enters SMM. Maskable hardware interrupts, exceptions, single-step traps, and breakpoint traps can be enabled in SMM if the SMM execution environment provides and initializes an interrupt table and the necessary interrupt and exception handlers (see Section 32.6).

### 32.5.2 SMI Handler Operating Mode Switching

Within SMM, an SMI handler may change the processor's operating mode (e.g., to enable PAE paging, enter 64-bit mode, etc.) after it has made proper preparation and initialization to do so. For example, if switching to 32-bit protected mode, the SMI handler should follow the guidelines provided in Chapter 10, "Processor Management and Initialization." If the SMI handler does wish to change operating mode, it is responsible for executing the appropriate mode-transition code after each SMI.

It is recommended that the SMI handler make use of all means available to protect the integrity of its critical code and data. In particular, it should use the system-management range register (SMRR) interface if it is available (see Section 11.11.2.4). The SMRR interface can protect only the first 4 GBytes of the physical address space. The SMI handler should take that fact into account if it uses operating modes that allow access to physical addresses beyond that 4-GByte limit (e.g., PAE paging or 64-bit mode).

Execution of the RSM instruction restores the pre-SMI processor state from the SMRAM state-state map (see Section 32.4.1) into which it was stored when the processor entered SMM. (The SMBASE field in the SMRAM state-save map does not determine the state following RSM but rather the initial environment following the next entry to SMM.) Any required change to operating mode is performed by the RSM instruction; there is no need for the SMI handler to change modes explicitly prior to executing RSM.

### 32.5.3 Control-flow Enforcement Technology Interactions

On processors that support CET shadow stacks, when the processor enters SMM, the processor saves the SSP register to the SMRAM state save area (see Table 32-3) and clears CR4.CET to 0. Thus, the initial execution environment of the SMI handler has CET disabled and all of the CET state of the interrupted program is still in the machine. An SMM that uses CET is required to save the interrupted program's CET state and restore the CET state prior to exiting SMM.

## 32.6 EXCEPTIONS AND INTERRUPTS WITHIN SMM

When the processor enters SMM, all hardware interrupts are disabled in the following manner:

- The IF flag in the EFLAGS register is cleared, which inhibits maskable hardware interrupts from being generated.
- The TF flag in the EFLAGS register is cleared, which disables single-step traps.
- Debug register DR7 is cleared, which disables breakpoint traps. (This action prevents a debugger from accidentally breaking into an SMI handler if a debug breakpoint is set in normal address space that overlays code or data in SMRAM.)
- NMI, SMI, and A20M interrupts are blocked by internal SMM logic. (See Section 32.8 for more information about how NMIs are handled in SMM.)

Software-invoked interrupts and exceptions can still occur, and maskable hardware interrupts can be enabled by setting the IF flag. Intel recommends that SMM code be written in so that it does not invoke software interrupts (with the INT *n*, INTO, INT1, INT3, or BOUND instructions) or generate exceptions.

If the SMI handler requires interrupt and exception handling, an SMM interrupt table and the necessary exception and interrupt handlers must be created and initialized from within SMM. Until the interrupt table is correctly initialized (using the LIDT instruction), exceptions and software interrupts will result in unpredictable processor behavior.

The following restrictions apply when designing SMM interrupt and exception-handling facilities:

- The interrupt table should be located at linear address 0 and must contain real-address mode style interrupt vectors (4 bytes containing CS and IP).
- Due to the real-address mode style of base address formation, an interrupt or exception cannot transfer control to a segment with a base address of more than 20 bits.
- An interrupt or exception cannot transfer control to a segment offset of more than 16 bits (64 KBytes).
- When an exception or interrupt occurs, only the 16 least-significant bits of the return address (EIP) are pushed onto the stack. If the offset of the interrupted procedure is greater than 64 KBytes, it is not possible for the interrupt/exception handler to return control to that procedure. (One solution to this problem is for a handler to adjust the return address on the stack.)
- The SMBASE relocation feature affects the way the processor will return from an interrupt or exception generated while the SMI handler is executing. For example, if the SMBASE is relocated to above 1 MByte, but the exception handlers are below 1 MByte, a normal return to the SMI handler is not possible. One solution is to provide the exception handler with a mechanism for calculating a return address above 1 MByte from the 16-bit return address on the stack, then use a 32-bit far call to return to the interrupted procedure.
- If an SMI handler needs access to the debug trap facilities, it must ensure that an SMM accessible debug handler is available and save the current contents of debug registers DR0 through DR3 (for later restoration). Debug registers DR0 through DR3 and DR7 must then be initialized with the appropriate values.
- If an SMI handler needs access to the single-step mechanism, it must ensure that an SMM accessible single-step handler is available, and then set the TF flag in the EFLAGS register.
- If the SMI design requires the processor to respond to maskable hardware interrupts or software-generated interrupts while in SMM, it must ensure that SMM accessible interrupt handlers are available and then set the IF flag in the EFLAGS register (using the STI instruction). Software interrupts are not blocked upon entry to SMM, so they do not need to be enabled.

## 32.7 MANAGING SYNCHRONOUS AND ASYNCHRONOUS SYSTEM MANAGEMENT INTERRUPTS

When coding for a multiprocessor system or a system with Intel HT Technology, it was not always possible for an SMI handler to distinguish between a synchronous SMI (triggered during an I/O instruction) and an asynchronous SMI. To facilitate the discrimination of these two events, incremental state information has been added to the SMM state save map.

Processors that have an SMM revision ID of 30004H or higher have the incremental state information described below.

### 32.7.1 I/O State Implementation

Within the extended SMM state save map, a bit (IO\_SMI) is provided that is set only when an SMI is either taken immediately after a *successful* I/O instruction or is taken after a *successful* iteration of a REP I/O instruction (the *successful* notion pertains to the processor point of view; not necessarily to the corresponding platform function). When set, the IO\_SMI bit provides a strong indication that the corresponding SMI was synchronous. In this case, the SMM State Save Map also supplies the port address of the I/O operation. The IO\_SMI bit and the I/O Port Address may be used in conjunction with the information logged by the platform to confirm that the SMI was indeed synchronous.

The IO\_SMI bit by itself is a strong indication, not a guarantee, that the SMI is synchronous. This is because an asynchronous SMI might coincidentally be taken after an I/O instruction. In such a case, the IO\_SMI bit would still be set in the SMM state save map.

Information characterizing the I/O instruction is saved in two locations in the SMM State Save Map (Table 32-5). The IO\_SMI bit also serves as a valid bit for the rest of the I/O information fields. The contents of these I/O information fields are not defined when the IO\_SMI bit is not set.

**Table 32-5. I/O Instruction Information in the SMM State Save Map**

| State (SMM Rev. ID: 30004H or higher)         | Format             |    |          |   |          |   |          |   |            |
|-----------------------------------------------|--------------------|----|----------|---|----------|---|----------|---|------------|
|                                               | 31                 | 16 | 15       | 8 | 7        | 4 | 3        | 1 | 0          |
| I/O State Field<br>SMRAM offset 7FA4          |                    |    | I/O Port |   | Reserved |   | I/O Type |   | I/O Length |
|                                               | 31                 |    |          |   |          |   |          |   | 0          |
| I/O Memory Address Field<br>SMRAM offset 7FA0 | I/O Memory Address |    |          |   |          |   |          |   |            |

When IO\_SMI is set, the other fields may be interpreted as follows:

- I/O length:
  - 001 – Byte
  - 010 – Word
  - 100 – Dword
- I/O instruction type (Table 32-6)

**Table 32-6. I/O Instruction Type Encodings**

| Instruction   | Encoding |
|---------------|----------|
| IN Immediate  | 1001     |
| IN DX         | 0001     |
| OUT Immediate | 1000     |

**Table 32-6. I/O Instruction Type Encodings (Contd.)**

| Instruction | Encoding |
|-------------|----------|
| OUT DX      | 0000     |
| INS         | 0011     |
| OUTS        | 0010     |
| REP INS     | 0111     |
| REP OUTS    | 0110     |

## 32.8 NMI HANDLING WHILE IN SMM

NMI interrupts are blocked upon entry to the SMI handler. If an NMI request occurs during the SMI handler, it is latched and serviced after the processor exits SMM. Only one NMI request will be latched during the SMI handler. If an NMI request is pending when the processor executes the RSM instruction, the NMI is serviced before the next instruction of the interrupted code sequence. This assumes that NMIs were not blocked before the SMI occurred. If NMIs were blocked before the SMI occurred, they are blocked after execution of RSM.

Although NMI requests are blocked when the processor enters SMM, they may be enabled through software by executing an IRET instruction. If the SMI handler requires the use of NMI interrupts, it should invoke a dummy interrupt service routine for the purpose of executing an IRET instruction. Once an IRET instruction is executed, NMI interrupt requests are serviced in the same “real mode” manner in which they are handled outside of SMM.

Also, for the Pentium processor, exceptions that invoke a trap or fault handler will enable NMI interrupts from inside of SMM. This behavior is implementation specific for the Pentium processor and is not part of the IA-32 architecture.

## 32.9 SMM REVISION IDENTIFIER

The SMM revision identifier field is used to indicate the version of SMM and the SMM extensions that are supported by the processor (see Figure 32-2). The SMM revision identifier is written during SMM entry and can be examined in SMRAM space at offset 7EFCH. The lower word of the SMM revision identifier refers to the version of the base SMM architecture.

**Figure 32-2. SMM Revision Identifier**

The upper word of the SMM revision identifier refers to the extensions available. If the I/O instruction restart flag (bit 16) is set, the processor supports the I/O instruction restart (see Section 32.12); if the SMBASE relocation flag (bit 17) is set, SMRAM base address relocation is supported (see Section 32.11).

## 32.10 AUTO HALT RESTART

If the processor is in a HALT state (due to the prior execution of a HLT instruction) when it receives an SMI, the processor records the fact in the auto HALT restart flag in the saved processor state (see Figure 32-3). (This flag is located at offset 7F02H and bit 0 in the state save area of the SMRAM.)

If the processor sets the auto HALT restart flag upon entering SMM (indicating that the SMI occurred when the processor was in the HALT state), the SMI handler has two options:

- It can leave the auto HALT restart flag set, which instructs the RSM instruction to return program control to the HLT instruction. This option in effect causes the processor to re-enter the HALT state after handling the SMI. (This is the default operation.)
- It can clear the auto HALT restart flag, which instructs the RSM instruction to return program control to the instruction following the HLT instruction.

**Figure 32-3. Auto HALT Restart Field**

These options are summarized in Table 32-7. If the processor was not in a HALT state when the SMI was received (the auto HALT restart flag is cleared), setting the flag to 1 will cause unpredictable behavior when the RSM instruction is executed.

**Table 32-7. Auto HALT Restart Flag Values**

| Value of Flag After Entry to SMM | Value of Flag When Exiting SMM | Action of Processor When Exiting SMM                        |
|----------------------------------|--------------------------------|-------------------------------------------------------------|
| 0                                | 0                              | Returns to next instruction in interrupted program or task. |
| 0                                | 1                              | Unpredictable.                                              |
| 1                                | 0                              | Returns to next instruction after HLT instruction.          |
| 1                                | 1                              | Returns to HALT state.                                      |

If the HLT instruction is restarted, the processor will generate a memory access to fetch the HLT instruction (if it is not in the internal cache), and execute a HLT bus transaction. This behavior results in multiple HLT bus transactions for the same HLT instruction.

### 32.10.1 Executing the HLT Instruction in SMM

The HLT instruction should not be executed during SMM, unless interrupts have been enabled by setting the IF flag in the EFLAGS register. If the processor is halted in SMM, the only event that can remove the processor from this state is a maskable hardware interrupt or a hardware reset.

## 32.11 SMBASE RELOCATION

The default base address for the SMRAM is 30000H. This value is contained in an internal processor register called the SMBASE register. The operating system or executive can relocate the SMRAM by setting the SMBASE field in the saved state map (at offset 7EF8H) to a new value (see Figure 32-4). The RSM instruction reloads the internal SMBASE register with the value in the SMBASE field each time it exits SMM. All subsequent SMI requests will use the new SMBASE value to find the starting address for the SMI handler (at SMBASE + 8000H) and the SMRAM state

save area (from SMBASE + FE00H to SMBASE + FFFFH). (The processor resets the value in its internal SMBASE register to 30000H on a RESET, but does not change it on an INIT.)

**Figure 32-4. SMBASE Relocation Field**

In multiple-processor systems, initialization software must adjust the SMBASE value for each processor so that the SMRAM state save areas for each processor do not overlap. (For Pentium and Intel486 processors, the SMBASE values must be aligned on a 32-KByte boundary or the processor will enter shutdown state during the execution of a RSM instruction.)

If the SMBASE relocation flag in the SMM revision identifier field is set, it indicates the ability to relocate the SMBASE (see Section 32.9).

## 32.12 I/O INSTRUCTION RESTART

If the I/O instruction restart flag in the SMM revision identifier field is set (see Section 32.9), the I/O instruction restart mechanism is present on the processor. This mechanism allows an interrupted I/O instruction to be re-executed upon returning from SMM mode. For example, if an I/O instruction is used to access a powered-down I/O device, a chipset supporting this device can intercept the access and respond by asserting SMI#. This action invokes the SMI handler to power-up the device. Upon returning from the SMI handler, the I/O instruction restart mechanism can be used to re-execute the I/O instruction that caused the SMI.

The I/O instruction restart field (at offset 7F00H in the SMM state-save area, see Figure 32-5) controls I/O instruction restart. When an RSM instruction is executed, if this field contains the value FFH, then the EIP register is modified to point to the I/O instruction that received the SMI request. The processor will then automatically re-execute the I/O instruction that the SMI trapped. (The processor saves the necessary machine state to ensure that re-execution of the instruction is handled coherently.)

**Figure 32-5. I/O Instruction Restart Field**

If the I/O instruction restart field contains the value 00H when the RSM instruction is executed, then the processor begins program execution with the instruction following the I/O instruction. (When a repeat prefix is being used, the next instruction may be the next I/O instruction in the repeat loop.) Not re-executing the interrupted I/O instruction is the default behavior; the processor automatically initializes the I/O instruction restart field to 00H upon entering SMM. Table 32-8 summarizes the states of the I/O instruction restart field.

**Table 32-8. I/O Instruction Restart Field Values**

| Value of Flag After Entry to SMM | Value of Flag When Exiting SMM | Action of Processor When Exiting SMM         |
|----------------------------------|--------------------------------|----------------------------------------------|
| 00H                              | 00H                            | Does not re-execute trapped I/O instruction. |
| 00H                              | FFH                            | Re-executes trapped I/O instruction.         |

The I/O instruction restart mechanism does not indicate the cause of the SMI. It is the responsibility of the SMI handler to examine the state of the processor to determine the cause of the SMI and to determine if an I/O instruction was interrupted and should be restarted upon exiting SMM. If an SMI interrupt is signaled on a non-I/O instruction boundary, setting the I/O instruction restart field to FFH prior to executing the RSM instruction will likely result in a program error.

### 32.12.1 Back-to-Back SMI Interrupts When I/O Instruction Restart Is Being Used

If an SMI interrupt is signaled while the processor is servicing an SMI interrupt that occurred on an I/O instruction boundary, the processor will service the new SMI request before restarting the originally interrupted I/O instruction. If the I/O instruction restart field is set to FFH prior to returning from the second SMI handler, the EIP will point to an address different from the originally interrupted I/O instruction, which will likely lead to a program error. To avoid this situation, the SMI handler must be able to recognize the occurrence of back-to-back SMI interrupts when I/O instruction restart is being used and ensure that the handler sets the I/O instruction restart field to 00H prior to returning from the second invocation of the SMI handler.

## 32.13 SMM MULTIPLE-PROCESSOR CONSIDERATIONS

The following should be noted when designing multiple-processor systems:

- Any processor in a multiprocessor system can respond to an SMI.
- Each processor needs its own SMRAM space. This space can be in system memory or in a separate RAM.
- The SMRAMs for different processors can be overlapped in the same memory space. The only stipulation is that each processor needs its own state save area and its own dynamic data storage area. (Also, for the Pentium and Intel486 processors, the SMBASE address must be located on a 32-KByte boundary.) Code and static data can be shared among processors. Overlapping SMRAM spaces can be done more efficiently with the P6 family processors because they do not require that the SMBASE address be on a 32-KByte boundary.
- The SMI handler will need to initialize the SMBASE for each processor.
- Processors can respond to local SMIs through their SMI# pins or to SMIs received through the APIC interface. The APIC interface can distribute SMIs to different processors.
- Two or more processors can be executing in SMM at the same time.
- When operating Pentium processors in dual processing (DP) mode, the SMIACT# pin is driven only by the MRM processor and should be sampled with ADS#. For additional details, see Chapter 14 of the *Pentium Processor Family User's Manual, Volume 1*.

SMM is not re-entrant, because the SMRAM State Save Map is fixed relative to the SMBASE. If there is a need to support two or more processors in SMM mode at the same time then each processor should have dedicated SMRAM spaces. This can be done by using the SMBASE Relocation feature (see Section 32.11).

## 32.14 DEFAULT TREATMENT OF SMIS AND SMM WITH VMX OPERATION AND SMX OPERATION

Under the default treatment, the interactions of SMIs and SMM with VMX operation are few. This section details those interactions. It also explains how this treatment affects SMX operation.

### 32.14.1 Default Treatment of SMI Delivery

Ordinary SMI delivery saves processor state into SMRAM and then loads state based on architectural definitions. Under the default treatment, processors that support VMX operation perform SMI delivery as follows:

```

enter SMM;
save the following internal to the processor:
 CR4.VMXE
 an indication of whether the logical processor was in VMX operation (root or non-root)
IF the logical processor is in VMX operation
 THEN
 save current VMCS pointer internal to the processor;
 leave VMX operation;
 save VMX-critical state defined below;
 F;
IF the logical processor supports SMX operation
 THEN
 save internal to the logical processor an indication of whether the Intel® TXT private space is locked;
 IF the TXT private space is unlocked
 THEN lock the TXT private space;
 F;
 F;
CR4.VMXE := 0;
perform ordinary SMI delivery:
 save processor state in SMRAM;
 set processor state to standard SMM values;1
 invalidate linear mappings and combined mappings associated with VPID 0000H (for all PCIDs); combined mappings for VPID 0000H are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP; see Section 29.4);

```

The pseudocode above makes reference to the saving of **VMX-critical state**. This state consists of the following: (1) SS.DPL (the current privilege level); (2) RFLAGS.VM<sup>2</sup>; (3) the state of blocking by STI and by MOV SS (see Table 25-3 in Section 25.4.2); (4) the state of virtual-NMI blocking (only if the processor is in VMX non-root operation and the “virtual NMIs” VM-execution control is 1); and (5) an indication of whether an MTF VM exit is pending (see Section 26.5.2). These data may be saved internal to the processor or in the VMCS region of the current VMCS. Processors that do not support SMI recognition while there is blocking by STI or by MOV SS need not save the state of such blocking.

If the logical processor supports the 1-setting of the “enable EPT” VM-execution control and the logical processor was in VMX non-root operation at the time of an SMI, it saves the value of that control into bit 0 of the 32-bit field at offset SMBASE + 8000H + 7EE0H (SMBASE + FEE0H; see Table 32-3).<sup>3</sup> If the logical processor was not in VMX non-root operation at the time of the SMI, it saves 0 into that bit. If the logical processor saves 1 into that bit (it was in VMX non-root operation and the “enable EPT” VM-execution control was 1), it saves the value of the EPT pointer (EPTP) into the 64-bit field at offset SMBASE + 8000H + 7ED8H (SMBASE + FED8H).

Because SMI delivery causes a logical processor to leave VMX operation, all the controls associated with VMX non-root operation are disabled in SMM and thus cannot cause VM exits while the logical processor in SMM.

- 
1. This causes the logical processor to block INIT signals, NMIs, and SMIs.
  2. Section 32.14 and Section 32.15 use the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of these registers (EAX, EIP, ESP, EFLAGS, etc.). In a few places, notation such as EAX is used to refer specifically to the lower 32 bits of the register.
  3. “Enable EPT” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, SMI functions as the “enable EPT” VM-execution control were 0. See Section 25.6.2.

### 32.14.2 Default Treatment of RSM

Ordinary execution of RSM restores processor state from SMRAM. Under the default treatment, processors that support VMX operation perform RSM as follows:

```

IF VMXE = 1 in CR4 image in SMRAM
 THEN fail and enter shutdown state;
 ELSE
 restore state normally from SMRAM;
 invalidate linear mappings and combined mappings associated with all VPIDs and all PCIDs; combined mappings are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP; see Section 29.4);
 IF the logical processor supports SMX operation and the Intel® TXT private space was unlocked at the time of the last SMI (as saved)
 THEN unlock the TXT private space;
 FI;
 CR4.VMXE := value stored internally;
 IF internal storage indicates that the logical processor had been in VMX operation (root or non-root)
 THEN
 enter VMX operation (root or non-root);
 restore VMX-critical state as defined in Section 32.14.1;
 set to their fixed values any bits in CRO and CR4 whose values must be fixed in VMX operation (see Section 24.8);1
 IF RFLAGS.VM = 0 AND (in VMX root operation OR the “unrestricted guest” VM-execution control is 0)2
 THEN
 CS.RPL := SS.DPL;
 SS.RPL := SS.DPL;
 FI;
 restore current VMCS pointer;
 FI;
 leave SMM;
 IF logical processor will be in VMX operation or in SMX operation after RSM
 THEN block A20M and leave A20M mode;
 FI;
 FI;

```

RSM unblocks SMIs. It restores the state of blocking by NMI (see Table 25-3 in Section 25.4.2) as follows:

- If the RSM is not to VMX non-root operation or if the “virtual NMIs” VM-execution control will be 0, the state of NMI blocking is restored normally.
- If the RSM is to VMX non-root operation and the “virtual NMIs” VM-execution control will be 1, NMIs are not blocked after RSM. The state of virtual-NMI blocking is restored as part of VMX-critical state.

INIT signals are blocked after RSM if and only if the logical processor will be in VMX root operation.

If RSM returns a logical processor to VMX non-root operation, it re-establishes the controls associated with the current VMCS. If the “interrupt-window exiting” VM-execution control is 1, a VM exit occurs immediately after RSM if the enabling conditions apply. The same is true for the “NMI-window exiting” VM-execution control. Such VM exits occur with their normal priority. See Section 26.2.

If an MTF VM exit was pending at the time of the previous SMI, an MTF VM exit is pending on the instruction boundary following execution of RSM. The following items detail the treatment of MTF VM exits that may be pending following RSM:

- 
1. If the RSM is to VMX non-root operation and both the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls will be 1, CRO.PE and CRO.PG retain the values that were loaded from SMRAM regardless of what is reported in the capability MSR IA32\_VMX\_CRO\_FIXED0.
  2. “Unrestricted guest” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions act as if the “unrestricted guest” VM-execution control were 0. See Section 25.6.2.

- System-management interrupts (SMIs), INIT signals, and higher priority events take priority over these MTF VM exits. These MTF VM exits take priority over debug-trap exceptions and lower priority events.
- These MTF VM exits wake the logical processor if RSM caused the logical processor to enter the HLT state (see Section 32.10). They do not occur if the logical processor just entered the shutdown state.

### 32.14.3 Protection of CR4.VMXE in SMM

Under the default treatment, CR4.VMXE is treated as a reserved bit while a logical processor is in SMM. Any attempt by software running in SMM to set this bit causes a general-protection exception. In addition, software cannot use VMX instructions or enter VMX operation while in SMM.

### 32.14.4 VMXOFF and SMI Unblocking

The VMXOFF instruction can be executed only with the default treatment (see Section 32.15.1) and only outside SMM. If SMIs are blocked when VMXOFF is executed, VMXOFF unblocks them unless IA32\_SMM\_MONITOR\_CTL[bit 2] is 1 (see Section 32.15.5 for details regarding this MSR).<sup>1</sup> Section 32.15.7 identifies a case in which SMIs may be blocked when VMXOFF is executed.

Not all processors allow this bit to be set to 1. Software should consult the VMX capability MSR IA32\_VMX\_MISC (see Appendix A.6) to determine whether this is allowed.

## 32.15 DUAL-MONITOR TREATMENT OF SMIs AND SMM

Dual-monitor treatment is activated through the cooperation of the **executive monitor** (the VMM that operates outside of SMM to provide basic virtualization) and the **SMM-transfer monitor (STM)** (the VMM that operates inside SMM—while in VMX operation—to support system-management functions). Control is transferred to the STM through VM exits; VM entries are used to return from SMM.

The dual-monitor treatment may not be supported by all processors. Software should consult the VMX capability MSR IA32\_VMX\_BASIC (see Appendix A.1) to determine whether it is supported.

### 32.15.1 Dual-Monitor Treatment Overview

The dual-monitor treatment uses an executive monitor and an SMM-transfer monitor (STM). Transitions from the executive monitor or its guests to the STM are called **SMM VM exits** and are discussed in Section 32.15.2. SMM VM exits are caused by SMIs as well as executions of VMCALL in VMX root operation. The latter allow the executive monitor to call the STM for service.

The STM runs in VMX root operation and uses VMX instructions to establish a VMCS and perform VM entries to its own guests. This is done all inside SMM (see Section 32.15.3). The STM returns from SMM, not by using the RSM instruction, but by using a VM entry that returns from SMM. Such VM entries are described in Section 32.15.4.

Initially, there is no STM and the default treatment (Section 32.14) is used. The dual-monitor treatment is not used until it is enabled and activated. The steps to do this are described in Section 32.15.5 and Section 32.15.6.

It is not possible to leave VMX operation under the dual-monitor treatment; VMXOFF will fail if executed. The dual-monitor treatment must be deactivated first. The STM deactivates dual-monitor treatment using a VM entry that returns from SMM with the “deactivate dual-monitor treatment” VM-entry control set to 1 (see Section 32.15.7).

The executive monitor configures any VMCS that it uses for VM exits to the executive monitor. SMM VM exits, which transfer control to the STM, use a different VMCS. Under the dual-monitor treatment, each logical processor uses a separate VMCS called the **SMM-transfer VMCS**. When the dual-monitor treatment is active, the logical processor maintains another VMCS pointer called the **SMM-transfer VMCS pointer**. The SMM-transfer VMCS pointer is established when the dual-monitor treatment is activated.

---

1. Setting IA32\_SMM\_MONITOR\_CTL[bit 2] to 1 prevents VMXOFF from unblocking SMIs regardless of the value of the register’s valid bit (bit 0).

## 32.15.2 SMM VM Exits

An SMM VM exit is a VM exit that begins outside SMM and that ends in SMM.

Unlike other VM exits, SMM VM exits can begin in VMX root operation. SMM VM exits result from the arrival of an SMI outside SMM or from execution of VMCALL in VMX root operation outside SMM. Execution of VMCALL in VMX root operation causes an SMM VM exit only if the valid bit is set in the IA32\_SMM\_MONITOR\_CTL MSR (see Section 32.15.5).

Execution of VMCALL in VMX root operation causes an SMM VM exit even under the default treatment. This SMM VM exit activates the dual-monitor treatment (see Section 32.15.6).

Differences between SMM VM exits and other VM exits are detailed in Sections 32.15.2.1 through 32.15.2.5. Differences between SMM VM exits that activate the dual-monitor treatment and other SMM VM exits are described in Section 32.15.6.

### 32.15.2.1 Architectural State Before a VM Exit

System-management interrupts (SMIs) that cause SMM VM exits always do so directly. They do not save state to SMRAM as they do under the default treatment.

### 32.15.2.2 Updating the Current-VMCS and Executive-VMCS Pointers

SMM VM exits begin by performing the following steps:

1. The executive-VMCS pointer field in the SMM-transfer VMCS is loaded as follows:
  - If the SMM VM exit commenced in VMX non-root operation, it receives the current-VMCS pointer.
  - If the SMM VM exit commenced in VMX root operation, it receives the VMXON pointer.
2. The current-VMCS pointer is loaded with the value of the SMM-transfer VMCS pointer.

The last step ensures that the current VMCS is the SMM-transfer VMCS. VM-exit information is recorded in that VMCS, and VM-entry control fields in that VMCS are updated. State is saved into the guest-state area of that VMCS. The VM-exit controls and host-state area of that VMCS determine how the VM exit operates.

### 32.15.2.3 Recording VM-Exit Information

SMM VM exits differ from other VM exit with regard to the way they record VM-exit information. The differences follow.

- **Exit reason.**
  - Bits 15:0 of this field contain the basic exit reason. The field is loaded with the reason for the SMM VM exit: I/O SMI (an SMI arrived immediately after retirement of an I/O instruction), other SMI, or VMCALL. See Appendix C, “VMX Basic Exit Reasons.”
  - SMM VM exits are the only VM exits that may occur in VMX root operation. Because the SMM-transfer monitor may need to know whether it was invoked from VMX root or VMX non-root operation, this information is stored in bit 29 of the exit-reason field (see Table 25-17 in Section 25.9.1). The bit is set by SMM VM exits from VMX root operation.
  - If the SMM VM exit occurred in VMX non-root operation and an MTF VM exit was pending, bit 28 of the exit-reason field is set; otherwise, it is cleared.
  - Bits 27:16 and bits 31:30 are cleared.
- **Exit qualification.** For an SMM VM exit due an SMI that arrives immediately after the retirement of an I/O instruction, the exit qualification contains information about the I/O instruction that retired immediately before the SMI. It has the format given in Table 32-9.
- **Guest linear address.** This field is used for VM exits due to SMIs that arrive immediately after the retirement of an INS or OUTS instruction for which the relevant segment (ES for INS; DS for OUTS unless overridden by an instruction prefix) is usable. The field receives the value of the linear address generated by ES:(E)DI (for INS) or segment:(E)SI (for OUTS; the default segment is DS but can be overridden by a segment override

**Table 32-9. Exit Qualification for SMIs That Arrive Immediately After the Retirement of an I/O Instruction**

| Bit Position(s) | Contents                                                                                         |
|-----------------|--------------------------------------------------------------------------------------------------|
| 2:0             | Size of access:<br>0 = 1-byte<br>1 = 2-byte<br>3 = 4-byte<br><br>Other values not used.          |
| 3               | Direction of the attempted access (0 = OUT, 1 = IN)                                              |
| 4               | String instruction (0 = not string; 1 = string)                                                  |
| 5               | REP prefixed (0 = not REP; 1 = REP)                                                              |
| 6               | Operand encoding (0 = DX, 1 = immediate)                                                         |
| 15:7            | Reserved (cleared to 0)                                                                          |
| 31:16           | Port number (as specified in the I/O instruction)                                                |
| 63:32           | Reserved (cleared to 0). These bits exist only on processors that support Intel 64 architecture. |

prefix) at the time the instruction started. If the relevant segment is not usable, the value is undefined. On processors that support Intel 64 architecture, bits 63:32 are clear if the logical processor was not in 64-bit mode before the VM exit.

- **I/O RCX, I/O RSI, I/O RDI, and I/O RIP.** For an SMM VM exit due an SMI that arrives immediately after the retirement of an I/O instruction, these fields receive the values that were in RCX, RSI, RDI, and RIP, respectively, before the I/O instruction executed. Thus, the value saved for I/O RIP addresses the I/O instruction.

### 32.15.2.4 Saving Guest State

SMM VM exits save the contents of the SMBASE register into the corresponding field in the guest-state area.

The value of the VMX-preemption timer is saved into the corresponding field in the guest-state area if the “save VMX-preemption timer value” VM-exit control is 1. That field becomes undefined if, in addition, either the SMM VM exit is from VMX root operation or the SMM VM exit is from VMX non-root operation and the “activate VMX-preemption timer” VM-execution control is 0.

### 32.15.2.5 Updating State

If an SMM VM exit is from VMX non-root operation and the “Intel PT uses guest physical addresses” VM-execution control is 1, the IA32\_RTIT\_CTL MSR is cleared to 00000000\_00000000H.<sup>1</sup> This is done even if the “clear IA32\_RTIT\_CTL” VM-exit control is 0.

SMM VM exits affect the non-register state of a logical processor as follows:

- SMM VM exits cause non-maskable interrupts (NMIs) to be blocked; they may be unblocked through execution of IRET or through a VM entry (depending on the value loaded for the interruptibility state and the setting of the “virtual NMIs” VM-execution control).
- SMM VM exits cause SMIs to be blocked; they may be unblocked by a VM entry that returns from SMM (see Section 32.15.4).

---

1. In this situation, the value of this MSR was saved earlier into the guest-state area. All VM exits save this MSR if the 1-setting of the “load IA32\_RTIT\_CTL” VM-entry control is supported (see Section 28.3.1), which must be the case if the “Intel PT uses guest physical addresses” VM-execution control is 1 (see Section 27.2.1.1).

SMM VM exits invalidate linear mappings and combined mappings associated with VPID 0000H for all PCIDs. Combined mappings for VPID 0000H are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP; see Section 29.4). (Ordinary VM exits are not required to perform such invalidation if the “enable VPID” VM-execution control is 1; see Section 28.5.5.)

### 32.15.3 Operation of the SMM-Transfer Monitor

Once invoked, the SMM-transfer monitor (STM) is in VMX root operation and can use VMX instructions to configure VMCSs and to cause VM entries to virtual machines supported by those structures. As noted in Section 32.15.1, the VMXOFF instruction cannot be used under the dual-monitor treatment and thus cannot be used by the STM.

The RSM instruction also cannot be used under the dual-monitor treatment. As noted in Section 26.1.3, it causes a VM exit if executed in SMM in VMX non-root operation. If executed in VMX root operation, it causes an invalid-opcode exception. The STM uses VM entries to return from SMM (see Section 32.15.4).

### 32.15.4 VM Entries that Return from SMM

The SMM-transfer monitor (STM) returns from SMM using a VM entry with the “entry to SMM” VM-entry control clear. VM entries that return from SMM reverse the effects of an SMM VM exit (see Section 32.15.2).

VM entries that return from SMM may differ from other VM entries in that they do not necessarily enter VMX non-root operation. If the executive-VMCS pointer field in the current VMCS contains the VMXON pointer, the logical processor remains in VMX root operation after VM entry.

For differences between VM entries that return from SMM and other VM entries see Sections 32.15.4.1 through 32.15.4.10.

#### 32.15.4.1 Checks on the Executive-VMCS Pointer Field

VM entries that return from SMM perform the following checks on the executive-VMCS pointer field in the current VMCS:

- Bits 11:0 must be 0.
- The pointer must not set any bits beyond the processor’s physical-address width.<sup>1,2</sup>
- The 32 bits located in memory referenced by the physical address in the pointer must contain the processor’s VMCS revision identifier (see Section 25.2).

The checks above are performed before the checks described in Section 32.15.4.2 and before any of the following checks:

- If the “deactivate dual-monitor treatment” VM-entry control is 0 and the executive-VMCS pointer field does not contain the VMXON pointer, the launch state of the executive VMCS (the VMCS referenced by the executive-VMCS pointer field) must be launched (see Section 25.11.3).
- If the “deactivate dual-monitor treatment” VM-entry control is 1, the executive-VMCS pointer field must contain the VMXON pointer (see Section 32.15.7).<sup>3</sup>

#### 32.15.4.2 Checks on VM-Execution Control Fields

VM entries that return from SMM differ from other VM entries with regard to the checks performed on the VM-execution control fields specified in Section 27.2.1.1. They do not apply the checks to the current VMCS. Instead, VM-entry behavior depends on whether the executive-VMCS pointer field contains the VMXON pointer:

- 
1. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
  2. If IA32\_VMX\_BASIC[48] is read as 1, this pointer must not set any bits in the range 63:32; see Appendix A.1.
  3. The STM can determine the VMXON pointer by reading the executive-VMCS pointer field in the current VMCS after the SMM VM exit that activates the dual-monitor treatment.

- If the executive-VMCS pointer field contains the VMXON pointer (the VM entry remains in VMX root operation), the checks are not performed at all.
- If the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation), the checks are performed on the VM-execution control fields in the executive VMCS (the VMCS referenced by the executive-VMCS pointer field in the current VMCS). These checks are performed after checking the executive-VMCS pointer field itself (for proper alignment).

Other VM entries ensure that, if “activate VMX-preemption timer” VM-execution control is 0, the “save VMX-preemption timer value” VM-exit control is also 0. This check is not performed by VM entries that return from SMM.

### 32.15.4.3 Checks on VM-Entry Control Fields

VM entries that return from SMM differ from other VM entries with regard to the checks performed on the VM-entry control fields specified in Section 27.2.1.3.

Specifically, if the executive-VMCS pointer field contains the VMXON pointer (the VM entry remains in VMX root operation), the VM-entry interruption-information field must not indicate injection of a pending MTF VM exit (see Section 27.6.2). Specifically, the following cannot all be true for that field:

- the valid bit (bit 31) is 1
- the interruption type (bits 10:8) is 7 (other event); and
- the vector (bits 7:0) is 0 (pending MTF VM exit).

### 32.15.4.4 Checks on the Guest State Area

Section 27.3.1 specifies checks performed on fields in the guest-state area of the VMCS. Some of these checks are conditioned on the settings of certain VM-execution controls (e.g., “virtual NMIs” or “unrestricted guest”).

VM entries that return from SMM modify these checks based on whether the executive-VMCS pointer field contains the VMXON pointer:<sup>1</sup>

- If the executive-VMCS pointer field contains the VMXON pointer (the VM entry remains in VMX root operation), the checks are performed as all relevant VM-execution controls were 0. (As a result, some checks may not be performed at all.)
- If the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation), this check is performed based on the settings of the VM-execution controls in the executive VMCS (the VMCS referenced by the executive-VMCS pointer field in the current VMCS).

For VM entries that return from SMM, the activity-state field must not indicate the wait-for-SIPI state if the executive-VMCS pointer field contains the VMXON pointer (the VM entry is to VMX root operation).

### 32.15.4.5 Loading Guest State

VM entries that return from SMM load the SMBASE register from the SMBASE field.

VM entries that return from SMM invalidate linear mappings and combined mappings associated with all VPIDs. Combined mappings are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP; see Section 29.4). (Ordinary VM entries are required to perform such invalidation only for VPID 0000H and are not required to do even that if the “enable VPID” VM-execution control is 1; see Section 27.3.2.5.)

### 32.15.4.6 VMX-Preemption Timer

A VM entry that returns from SMM activates the VMX-preemption timer only if the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation) and the “activate VMX-preemption timer” VM-execution control is 1 in the executive VMCS (the VMCS referenced by the executive-VMCS pointer field). In this case, VM entry starts the VMX-preemption timer with the value in the VMX-preemption timer-value field in the current VMCS.

---

1. The STM can determine the VMXON pointer by reading the executive-VMCS pointer field in the current VMCS after the SMM VM exit that activates the dual-monitor treatment.

### 32.15.4.7 Updating the Current-VMCS and SMM-Transfer VMCS Pointers

Successful VM entries (returning from SMM) load the SMM-transfer VMCS pointer with the current-VMCS pointer. Following this, they load the current-VMCS pointer from a field in the current VMCS:

- If the executive-VMCS pointer field contains the VMXON pointer (the VM entry remains in VMX root operation), the current-VMCS pointer is loaded from the VMCS-link pointer field.
- If the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation), the current-VMCS pointer is loaded with the value of the executive-VMCS pointer field.

If the VM entry successfully enters VMX non-root operation, the VM-execution controls in effect after the VM entry are those from the new current VMCS. This includes any structures external to the VMCS referenced by VM-execution control fields.

The updating of these VMCS pointers occurs before event injection. Event injection is determined, however, by the VM-entry control fields in the VMCS that was current when the VM entry commenced.

### 32.15.4.8 VM Exits Induced by VM Entry

Section 27.6.1.2 describes how the event-delivery process invoked by event injection may lead to a VM exit.

Section 27.7.3 to Section 27.7.7 describe other situations that may cause a VM exit to occur immediately after a VM entry.

Whether these VM exits occur is determined by the VM-execution control fields in the current VMCS. For VM entries that return from SMM, they can occur only if the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation).

In this case, determination is based on the VM-execution control fields in the VMCS that is current after the VM entry. This is the VMCS referenced by the value of the executive-VMCS pointer field at the time of the VM entry (see Section 32.15.4.7). This VMCS also controls the delivery of such VM exits. Thus, VM exits induced by a VM entry returning from SMM are to the executive monitor and not to the STM.

### 32.15.4.9 SMI Blocking

VM entries that return from SMM determine the blocking of system-management interrupts (SMIs) as follows:

- If the “deactivate dual-monitor treatment” VM-entry control is 0, SMIs are blocked after VM entry if and only if the bit 2 in the interruptibility-state field is 1.
- If the “deactivate dual-monitor treatment” VM-entry control is 1, the blocking of SMIs depends on whether the logical processor is in SMX operation:<sup>1</sup>
  - If the logical processor is in SMX operation, SMIs are blocked after VM entry.
  - If the logical processor is outside SMX operation, SMIs are unblocked after VM entry.

VM entries that return from SMM and that do not deactivate the dual-monitor treatment may leave SMIs blocked. This feature exists to allow the STM to invoke functionality outside of SMM without unblocking SMIs.

### 32.15.4.10 Failures of VM Entries That Return from SMM

Section 27.8 describes the treatment of VM entries that fail during or after loading guest state. Such failures record information in the VM-exit information fields and load processor state as would be done on a VM exit. The VMCS used is the one that was current before the VM entry commenced. Control is thus transferred to the STM and the logical processor remains in SMM.

---

1. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENTER]. A logical processor is outside SMX operation if GETSEC[SENTER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENTER]. See Chapter 7, “Safer Mode Extensions Reference,” in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2D.

### 32.15.5 Enabling the Dual-Monitor Treatment

Code and data for the SMM-transfer monitor (STM) reside in a region of SMRAM called the **monitor segment** (MSEG). Code running in SMM determines the location of MSEG and establishes its content. This code is also responsible for enabling the dual-monitor treatment.

SMM code enables the dual-monitor treatment and specifies the location of MSEG by writing to the IA32\_SMM\_MONITOR\_CTL MSR (index 9BH). The MSR has the following format:

- Bit 0 is the register's valid bit. The STM may be invoked using VMCALL only if this bit is 1. Because VMCALL is used to activate the dual-monitor treatment (see Section 32.15.6), the dual-monitor treatment cannot be activated if the bit is 0. This bit is cleared when the logical processor is reset.
- Bit 1 is reserved.
- Bit 2 determines whether executions of VMXOFF unblock SMIs under the default treatment of SMIs and SMM. Executions of VMXOFF unblock SMIs unless bit 2 is 1 (the value of bit 0 is irrelevant). See Section 32.14.4. Certain leaf functions of the GETSEC instruction clear this bit (see Chapter 7, "Safer Mode Extensions Reference," in the Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2D).
- Bits 11:3 are reserved.
- Bits 31:12 contain a value that, when shifted left 12 bits, is the physical address of MSEG (the MSEG base address).
- Bits 63:32 are reserved.

The following items detail use of this MSR:

- The IA32\_SMM\_MONITOR\_CTL MSR is supported only on processors that support the dual-monitor treatment.<sup>1</sup> On other processors, accesses to the MSR using RDMSR or WRMSR generate a general-protection fault (#GP(0)).
- A write to the IA32\_SMM\_MONITOR\_CTL MSR using WRMSR generates a general-protection fault (#GP(0)) if executed outside of SMM or if an attempt is made to set any reserved bit. An attempt to write to the IA32\_SMM\_MONITOR\_CTL MSR fails if made as part of a VM exit that does not end in SMM or part of a VM entry that does not begin in SMM.
- Reads from the IA32\_SMM\_MONITOR\_CTL MSR using RDMSR are allowed any time RDMSR is allowed. The MSR may be read as part of any VM exit.
- The dual-monitor treatment can be activated only if the valid bit in the MSR is set to 1.

The 32 bytes located at the MSEG base address are called the **MSEG header**. The format of the MSEG header is given in Table 32-10 (each field is 32 bits).

**Table 32-10. Format of MSEG Header**

| Byte Offset | Field                           |
|-------------|---------------------------------|
| 0           | MSEG-header revision identifier |
| 4           | SMM-transfer monitor features   |
| 8           | GDTR limit                      |
| 12          | GDTR base offset                |
| 16          | CS selector                     |
| 20          | EIP offset                      |
| 24          | ESP offset                      |
| 28          | CR3 offset                      |

1. Software should consult the VMX capability MSR IA32\_VMX\_BASIC (see Appendix A.1) to determine whether the dual-monitor treatment is supported.

To ensure proper behavior in VMX operation, software should maintain the MSEG header in writeback cacheable memory. Future implementations may allow or require a different memory type.<sup>1</sup> Software should consult the VMX capability MSR IA32\_VMX\_BASIC (see Appendix A.1).

SMM code should enable the dual-monitor treatment (by setting the valid bit in IA32\_SMM\_MONITOR\_CTL MSR) only after establishing the content of the MSEG header as follows:

- Bytes 3:0 contain the **MSEG revision identifier**. Different processors may use different MSEG revision identifiers. These identifiers enable software to avoid using an MSEG header formatted for one processor on a processor that uses a different format. Software can discover the MSEG revision identifier that a processor uses by reading the VMX capability MSR IA32\_VMX\_MISC (see Appendix A.6).
- Bytes 7:4 contain the **SMM-transfer monitor features** field. Bits 31:1 of this field are reserved and must be zero. Bit 0 of the field is the **IA-32e mode SMM feature bit**. It indicates whether the logical processor will be in IA-32e mode after the STM is activated (see Section 32.15.6).
- Bytes 31:8 contain fields that determine how processor state is loaded when the STM is activated (see Section 32.15.6.5). SMM code should establish these fields so that activating of the STM invokes the STM's initialization code.

## 32.15.6 Activating the Dual-Monitor Treatment

The dual-monitor treatment may be enabled by SMM code as described in Section 32.15.5. The dual-monitor treatment is activated only if it is enabled and only by the executive monitor. The executive monitor activates the dual-monitor treatment by executing VMCALL in VMX root operation.

When VMCALL activates the dual-monitor treatment, it causes an SMM VM exit. Differences between this SMM VM exit and other SMM VM exits are discussed in Sections 32.15.6.1 through 32.15.6.6. See also "VMCALL—Call to VM Monitor" in Chapter 31.

### 32.15.6.1 Initial Checks

An execution of VMCALL attempts to activate the dual-monitor treatment if (1) the processor supports the dual-monitor treatment;<sup>2</sup> (2) the logical processor is in VMX root operation; (3) the logical processor is outside SMM and the valid bit is set in the IA32\_SMM\_MONITOR\_CTL MSR; (4) the logical processor is not in virtual-8086 mode and not in compatibility mode; (5) CPL = 0; and (6) the dual-monitor treatment is not active.

Such an execution of VMCALL begins with some initial checks. These checks are performed before updating the current-VMCS pointer and the executive-VMCS pointer field (see Section 32.15.2.2).

The VMCS that manages SMM VM exit caused by this VMCALL is the current VMCS established by the executive monitor. The VMCALL performs the following checks on the current VMCS in the order indicated:

1. There must be a current VMCS pointer.
2. The launch state of the current VMCS must be clear.
3. The VM-exit controls in the current VMCS must be set properly:
  - Reserved bits in the primary VM-exit controls must be set properly. Software may consult the VMX capability MSRs to determine the proper setting (see Appendix A.4.1).
  - If the "activate secondary controls" primary VM-exit control is 1, reserved bits in the secondary VM-exit controls must be cleared. Software may consult the VMX capability MSRs to determine which bits are reserved (see Appendix A.4.2).

- 
1. Alternatively, software may map the MSEG header with the UC memory type; this may be necessary, depending on how memory is organized. Doing so is strongly discouraged unless necessary as it will cause the performance of transitions using those structures to suffer significantly. In addition, the processor will continue to use the memory type reported in the VMX capability MSR IA32\_VMX\_BASIC with exceptions noted in Appendix A.1.
  2. Software should consult the VMX capability MSR IA32\_VMX\_BASIC (see Appendix A.1) to determine whether the dual-monitor treatment is supported.

- If the “activate secondary controls” primary VM-exit control is 0 (or if the processor does not support the 1-setting of that control), no checks are performed on the secondary VM-exit controls. The logical processor operates as if all the secondary VM-exit controls were 0.

If any of these checks fail, subsequent checks are skipped and VMCALL fails. If all these checks succeed, the logical processor uses the IA32\_SMM\_MONITOR\_CTL MSR to determine the base address of MSEG. The following checks are performed in the order indicated:

1. The logical processor reads the 32 bits at the base of MSEG and compares them to the processor’s MSEG revision identifier.
2. The logical processor reads the SMM-transfer monitor features field:
  - Bit 0 of the field is the IA-32e mode SMM feature bit, and it indicates whether the logical processor will be in IA-32e mode after the SMM-transfer monitor (STM) is activated.
    - If the VMCALL is executed on a processor that does not support Intel 64 architecture, the IA-32e mode SMM feature bit must be 0.
    - If the VMCALL is executed in 64-bit mode, the IA-32e mode SMM feature bit must be 1.
  - Bits 31:1 of this field are currently reserved and must be zero.

If any of these checks fail, subsequent checks are skipped and the VMCALL fails.

### 32.15.6.2 Updating the Current-VMCS and Executive-VMCS Pointers

Before performing the steps in Section 32.15.2.2, SMM VM exits that activate the dual-monitor treatment begin by loading the SMM-transfer VMCS pointer with the value of the current-VMCS pointer.

### 32.15.6.3 Saving Guest State

As noted in Section 32.15.2.4, SMM VM exits save the contents of the SMBASE register into the corresponding field in the guest-state area. While this is true also for SMM VM exits that activate the dual-monitor treatment, the VMCS used for those VM exits exists outside SMRAM.

The SMM-transfer monitor (STM) can also discover the current value of the SMBASE register by using the RDMSR instruction to read the IA32\_SMBASE MSR (MSR address 9EH). The following items detail use of this MSR:

- The MSR is supported only if IA32\_VMX\_MISC[15] = 1 (see Appendix A.6).
- A write to the IA32\_SMBASE MSR using WRMSR generates a general-protection fault (#GP(0)). An attempt to write to the IA32\_SMBASE MSR fails if made as part of a VM exit or part of a VM entry.
- A read from the IA32\_SMBASE MSR using RDMSR generates a general-protection fault (#GP(0)) if executed outside of SMM. An attempt to read from the IA32\_SMBASE MSR fails if made as part of a VM exit that does not end in SMM.

### 32.15.6.4 Saving MSRs

The VM-exit MSR-store area is not used by SMM VM exits that activate the dual-monitor treatment. No MSRs are saved into that area.

### 32.15.6.5 Loading Host State

The VMCS that is current during an SMM VM exit that activates the dual-monitor treatment was established by the executive monitor. It does not contain the VM-exit controls and host state required to initialize the STM. For this reason, such SMM VM exits do not load processor state as described in Section 28.5. Instead, state is set to fixed values or loaded based on the content of the MSEG header (see Table 32-10):

- CR0 is set to as follows:
  - PG, NE, ET, MP, and PE are all set to 1.
  - CD and NW are left unchanged.

## SYSTEM MANAGEMENT MODE

- All other bits are cleared to 0.
- CR3 is set as follows:
  - Bits 63:32 are cleared on processors that support IA-32e mode.
  - Bits 31:12 are set to bits 31:12 of the sum of the MSEG base address and the CR3-offset field in the MSEG header.
  - Bits 11:5 and bits 2:0 are cleared (the corresponding bits in the CR3-offset field in the MSEG header are ignored).
  - Bits 4:3 are set to bits 4:3 of the CR3-offset field in the MSEG header.
- CR4 is set as follows:
  - MCE, PGE, CET, and PCIDE are cleared.
  - PAE is set to the value of the IA-32e mode SMM feature bit.
  - If the IA-32e mode SMM feature bit is clear, PSE is set to 1 if supported by the processor; if the bit is set, PSE is cleared.
  - All other bits are unchanged.
- DR7 is set to 400H.
- The IA32\_DEBUGCTL MSR is cleared to 00000000\_00000000H.
- The registers CS, SS, DS, ES, FS, and GS are loaded as follows:
  - All registers are usable.
  - CS.selector is loaded from the corresponding field in the MSEG header (the high 16 bits are ignored), with bits 2:0 cleared to 0. If the result is 0000H, CS.selector is set to 0008H.
  - The selectors for SS, DS, ES, FS, and GS are set to CS.selector+0008H. If the result is 0000H (if the CS selector was FFF8H), these selectors are instead set to 0008H.
  - The base addresses of all registers are cleared to zero.
  - The segment limits for all registers are set to FFFFFFFFH.
  - The AR bytes for the registers are set as follows:
    - CS.Type is set to 11 (execute/read, accessed, non-conforming code segment).
    - For SS, DS, ES, FS, and GS, the Type is set to 3 (read/write, accessed, expand-up data segment).
    - The S bits for all registers are set to 1.
    - The DPL for each register is set to 0.
    - The P bits for all registers are set to 1.
    - On processors that support Intel 64 architecture, CS.L is loaded with the value of the IA-32e mode SMM feature bit.
    - CS.D is loaded with the inverse of the value of the IA-32e mode SMM feature bit.
    - For each of SS, DS, ES, FS, and GS, the D/B bit is set to 1.
    - The G bits for all registers are set to 1.
  - LDTR is unusable. The LDTR selector is cleared to 0000H, and the register is otherwise undefined (although the base address is always canonical)
  - GDTR.base is set to the sum of the MSEG base address and the GDTR base-offset field in the MSEG header (bits 63:32 are always cleared on processors that support IA-32e mode). GDTR.limit is set to the corresponding field in the MSEG header (the high 16 bits are ignored).
  - IDTR.base is unchanged. IDTR.limit is cleared to 0000H.
  - RIP is set to the sum of the MSEG base address and the value of the RIP-offset field in the MSEG header (bits 63:32 are always cleared on logical processors that support IA-32e mode).
  - RSP is set to the sum of the MSEG base address and the value of the RSP-offset field in the MSEG header (bits 63:32 are always cleared on logical processor that supports IA-32e mode).

- RFLAGS is cleared, except bit 1, which is always set.
- The logical processor is left in the active state.
- Event blocking after the SMM VM exit is as follows:
  - There is no blocking by STI or by MOV SS.
  - There is blocking by non-maskable interrupts (NMIs) and by SMIs.
- There are no pending debug exceptions after the SMM VM exit.
- For processors that support IA-32e mode, the IA32\_EFER MSR is modified so that LME and LMA both contain the value of the IA-32e mode SMM feature bit.

If any of CR3[63:5], CR4.PAE, CR4.PSE, or IA32\_EFER.LMA is changing, the TLBs are updated so that, after VM exit, the logical processor does not use translations that were cached before the transition. This is not necessary for changes that would not affect paging due to the settings of other bits (for example, changes to CR4.PSE if IA32\_EFER.LMA was 1 before and after the transition).

### 32.15.6.6 Loading MSRs

The VM-exit MSR-load area is not used by SMM VM exits that activate the dual-monitor treatment. No MSRs are loaded from that area.

### 32.15.7 Deactivating the Dual-Monitor Treatment

The SMM-transfer monitor may deactivate the dual-monitor treatment and return the processor to default treatment of SMIs and SMM (see Section 32.14). It does this by executing a VM entry with the “deactivate dual-monitor treatment” VM-entry control set to 1.

As noted in Section 27.2.1.3 and Section 32.15.4.1, an attempt to deactivate the dual-monitor treatment fails in the following situations: (1) the processor is not in SMM; (2) the “entry to SMM” VM-entry control is 1; or (3) the executive-VMCS pointer does not contain the VMXON pointer (the VM entry is to VMX non-root operation).

As noted in Section 32.15.4.9, VM entries that deactivate the dual-monitor treatment ignore the SMI bit in the interruptibility-state field of the guest-state area. Instead, the blocking of SMIs following such a VM entry depends on whether the logical processor is in SMX operation:<sup>1</sup>

- If the logical processor is in SMX operation, SMIs are blocked after VM entry. SMIs may later be unblocked by the VMXOFF instruction (see Section 32.14.4) or by certain leaf functions of the GETSEC instruction (see Chapter 7, “Safer Mode Extensions Reference,” in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2D).
- If the logical processor is outside SMX operation, SMIs are unblocked after VM entry.

## 32.16 SMI AND PROCESSOR EXTENDED STATE MANAGEMENT

On processors that support processor extended states using XSAVE/XRSTOR (see Chapter 13, “Managing State Using the XSAVE Feature Set,” of the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1), the processor does not save any XSAVE/XRSTOR related state on an SMI. It is the responsibility of the SMI handler code to properly preserve the state information (including CR4.OSXSAVE, XCR0, and possibly processor extended states using XSAVE/XRSTOR). Therefore, the SMI handler must follow the rules described in Chapter 13, “Managing State Using the XSAVE Feature Set,” of the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1.

---

1. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENTER]. A logical processor is outside SMX operation if GETSEC[SENTER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENTER]. See Chapter 7, “Safer Mode Extensions Reference,” in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2D.

## 32.17 MODEL-SPECIFIC SYSTEM MANAGEMENT ENHANCEMENT

This section describes enhancement of system management features that apply only to the 4th generation Intel Core processors. These features are model-specific. BIOS and SMM handler must use CPUID to enumerate Display-Family\_DisplayModel signature when programming with these interfaces.

### 32.17.1 SMM Handler Code Access Control

The BIOS may choose to restrict the address ranges of code that SMM handler executes. When SMM handler code execution check is enabled, an attempt by the SMM handler to execute outside the ranges specified by SMRR (see Section 32.4.2.1) will cause the assertion of an unrecoverable machine check exception (MCE).

The interface to enable SMM handler code access check resides in a per-package scope model-specific register MSR\_SMM\_FEATURE\_CONTROL at address 4E0H. An attempt to access MSR\_SMM\_FEATURE\_CONTROL outside of SMM will cause a #GP. Writes to MSR\_SMM\_FEATURE\_CONTROL is further protected by configuration interface of MSR\_SMM\_MCA\_CAP at address 17DH.

Details of the interface of MSR\_SMM\_FEATURE\_CONTROL and MSR\_SMM\_MCA\_CAP are described in Table 2-29 in Chapter 2, "Model-Specific Registers (MSRs)," of the Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 4.

### 32.17.2 SMI Delivery Delay Reporting

Entry into the system management mode occurs at instruction boundary. In situations where a logical processor is executing an instruction involving a long flow of internal operations, servicing an SMI by that logical processor will be delayed. Delayed servicing of SMI of each logical processor due to executing long flows of internal operation in a physical processor can be queried via a package-scope register MSR\_SMM\_DELAYED at address 4E2H.

The interface to enable reporting of SMI delivery delay due to long internal flows resides in a per-package scope model-specific register MSR\_SMM\_DELAYED. An attempt to access MSR\_SMM\_DELAYED outside of SMM will cause a #GP. Availability to MSR\_SMM\_DELAYED is protected by configuration interface of MSR\_SMM\_MCA\_CAP at address 17DH.

Details of the interface of MSR\_SMM\_DELAYED and MSR\_SMM\_MCA\_CAP are described in Table 2-29 in Chapter 2, "Model-Specific Registers (MSRs)," of the Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 4.

### 32.17.3 Blocked SMI Reporting

A logical processor may have entered into a state and blocked from servicing other interrupts (including SMI). Logical processors in a physical processor that are blocked in serving SMI can be queried in a package-scope register MSR\_SMM\_BLOCKED at address 4E3H. An attempt to access MSR\_SMM\_BLOCKED outside of SMM will cause a #GP.

Details of the interface of MSR\_SMM\_BLOCKED is described in Table 2-29 in Chapter 2, "Model-Specific Registers (MSRs)," of the Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 4.

# CHAPTER 33

## INTEL® PROCESSOR TRACE

---

### 33.1 OVERVIEW

Intel® Processor Trace (**Intel PT**) is an extension of Intel® Architecture that captures information about software execution using dedicated hardware facilities that cause only minimal performance perturbation to the software being traced. This information is collected in **data packets**. The initial implementations of Intel PT offer **control flow tracing**, which generates a variety of packets to be processed by a software decoder. The packets include timing, program flow information (e.g., branch targets, branch taken/not taken indications) and program-induced mode related information (e.g., Intel TSX state transitions, CR3 changes). These packets may be buffered internally before being sent to the memory subsystem or other output mechanism available in the platform. Debug software can process the trace data and reconstruct the program flow.

Intel Processor Trace was first introduced in Intel® processors based on Broadwell microarchitecture and Intel Atom® processors based on Goldmont microarchitecture. Later generations include additional trace sources, including software trace instrumentation using PTWRITE, and Power Event tracing.

#### 33.1.1 Features and Capabilities

Intel PT's control flow trace generates a variety of packets that, when combined with the binaries of a program by a post-processing tool, can be used to produce an exact execution trace. The packets record flow information such as instruction pointers (IP), indirect branch targets, and directions of conditional branches within contiguous code regions (basic blocks).

Intel PT can also be configured to log software-generated packets using PTWRITE, and packets describing processor power management events. Further, Precise Event-Based Sampling (PEBS) can be configured to log PEBS records in the Intel PT trace; see Section 20.5.5.2.

In addition, the packets record other contextual, timing, and bookkeeping information that enables both functional and performance debugging of applications. Intel PT has several control and filtering capabilities available to customize the tracing information collected and to append other processor state and timing information to enable debugging. For example, there are modes that allow packets to be filtered based on the current privilege level (CPL) or the value of CR3.

Configuration of the packet generation and filtering capabilities are programmed via a set of MSRs. The MSRs generally follow the naming convention of IA32\_RTIT\_\*. The capability provided by these configuration MSRs are enumerated by CPUID, see Section 33.3. Details of the MSRs for configuring Intel PT are described in Section 33.2.8.

##### 33.1.1.1 Packet Summary

After a tracing tool has enabled and configured the appropriate MSRs, the processor will collect and generate trace information in the following categories of packets (for more details on the packets, see Section 33.4):

- Packets about basic information on program execution; these include:
  - Packet Stream Boundary (PSB) packets: PSB packets act as 'heartbeats' that are generated at regular intervals (e.g., every 4K trace packet bytes). These packets allow the packet decoder to find the packet boundaries within the output data stream; a PSB packet should be the first packet that a decoder looks for when beginning to decode a trace.
  - Paging Information Packet (PIP): PIPs record modifications made to the CR3 register. This information, along with information from the operating system on the CR3 value of each process, allows the debugger to attribute linear addresses to their correct application source.
  - Time-Stamp Counter (TSC) packets: TSC packets aid in tracking wall-clock time, and contain some portion of the software-visible time-stamp counter.
  - Core Bus Ratio (CBR) packets: CBR packets contain the core:bus clock ratio.

- Mini Time Counter (MTC) packets: MTC packets provide periodic indication of the passing of wall-clock time.
- Cycle Count (CYC) packets: CYC packets provide indication of the number of processor core clock cycles that pass between packets.
- Overflow (OVF) packets: OVF packets are sent when the processor experiences an internal buffer overflow, resulting in packets being dropped. This packet notifies the decoder of the loss and can help the decoder to respond to this situation.
- Packets about control flow information:
  - Taken Not-Taken (TNT) packets: TNT packets track the “direction” of direct conditional branches (taken or not taken).
  - Target IP (TIP) packets: TIP packets record the target IP of indirect branches, exceptions, interrupts, and other branches or events. These packets can contain the IP, although that IP value may be compressed by eliminating upper bytes that match the last IP. There are various types of TIP packets; they are covered in more detail in Section 33.4.2.2.
  - Flow Update Packets (FUP): FUPs provide the source IP addresses for asynchronous events (interrupt and exceptions), as well as other cases where the source address cannot be determined from the binary.
  - MODE packets: These packets provide the decoder with important processor execution information so that it can properly interpret the dis-assembled binary and trace log. MODE packets have a variety of formats that indicate details such as the execution mode (16-bit, 32-bit, or 64-bit).
- Packets inserted by software:
  - PTWRITE (PTW) packets: includes the value of the operand passed to the PTWRITE instruction (see “PTWRITE—Write Data to a Processor Trace Packet” in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B).
- Packets about processor power management events:
  - MWAIT packets: Indicate successful completion of an MWAIT operation to a C-state deeper than C0.0.
  - Power State Entry (PWRE) packets: Indicate entry to a C-state deeper than C0.0.
  - Power State Exit (PWRX) packets: Indicate exit from a C-state deeper than C0.0, returning to C0.
  - Execution Stopped (EXSTOP) packets: Indicate that software execution has stopped, due to events such as P-state change, C-state change, or thermal throttling.
- Packets containing groups of processor state values:
  - Block Begin Packets (BBP): Indicate the type of state held in the following group.
  - Block Item Packets (BIP): Indicate the state values held in the group.
  - Block End Packets (BEP): Indicate the end of the current group.

## 33.2 INTEL® PROCESSOR TRACE OPERATIONAL MODEL

This section describes the overall Intel Processor Trace mechanism and the essential concepts relevant to how it operates.

### 33.2.1 Change of Flow Instruction (COFI) Tracing

A basic program block is a section of code where no jumps or branches occur. The instruction pointers (IPs) in this block of code need not be traced, as the processor will execute them from start to end without redirecting code flow. Instructions such as branches, and events such as exceptions or interrupts, can change the program flow. These instructions and events that change program flow are called Change of Flow Instructions (COFI). There are three categories of COFI:

- Direct transfer COFI.
- Indirect transfer COFI.
- Far transfer COFI.

The following subsections describe the COFI events that result in trace packet generation. Table 33-1 lists branch instruction by COFI types. For detailed description of specific instructions, see the Intel® 64 and IA-32 Architectures Software Developer’s Manual.

**Table 33-1. COFI Type for Branch Instructions**

| COFI Type                   | Instructions                                                                                                                                                                                           |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Conditional Branch          | JA, JAE, JB, JBE, JC, JCXZ, JECXZ, JRCXZ, JE, JG, JGE, JL, JLE, JNA, JNAE, JNB, JNBE, JNC, JNE, JNG, JNGE, JNL, JNLE, JNO, JNP, JNS, JNZ, JO, JP, JPE, JPO, JS, JZ, LOOP, LOOPE, LOOPNE, LOOPNZ, LOOPZ |
| Unconditional Direct Branch | JMP (E9 xx, EB xx), CALL (E8 xx)                                                                                                                                                                       |
| Indirect Branch             | JMP (FF /4), CALL (FF /2), RET (C3, C2 xx)                                                                                                                                                             |
| Far Transfers               | INT1, INT3, INT n, INTO, IRET, IRETD, IRETN, JMP (EA xx, FF /5), CALL (9A xx, FF /3), RET (CB, CA xx), SYSCALL, SYSRET, SYSEXIT, VMLAUNCH, VMRESUME                                                    |

### 33.2.1.1 Direct Transfer COFI

Direct Transfer COFI are relative branches. This means that their target is an IP whose offset from the current IP is embedded in the instruction bytes. It is not necessary to indicate target of these instructions in the trace output since it can be obtained through the source disassembly. Conditional branches need to indicate only whether the branch is taken or not. Unconditional branches do not need any recording in the trace output. There are two sub-categories:

- **Conditional Branch (Jcc, J\*CXZ) and LOOP**

To track this type of instruction, the processor encodes a single bit (taken or not taken — TNT) to indicate the program flow after the instruction.

Jcc, J\*CXZ, and LOOP can be traced with TNT bits. To improve the trace packet output efficiency, the processor will compact several TNT bits into a single packet.

- **Unconditional Direct Jumps**

There is no trace output required for direct unconditional jumps (like JMP near relative or CALL near relative) since they can be directly inferred from the application assembly. Direct unconditional jumps do not generate a TNT bit or a Target IP packet, though TIP.PGD and TIP.PGE packets can be generated by unconditional direct jumps that toggle Intel PT enables (see Section 33.2.6).

### 33.2.1.2 Indirect Transfer COFI

Indirect transfer instructions involve updating the IP from a register or memory location. Since the register or memory contents can vary at any time during execution, there is no way to know the target of the indirect transfer until the register or memory contents are read. As a result, the disassembled code is not sufficient to determine the target of this type of COFI. Therefore, tracing hardware must send out the destination IP in the trace packet for debug software to determine the target address of the COFI. Note that this IP may be a linear or effective address (see Section 33.3.1.1).

An indirect transfer instruction generates a Target IP Packet (TIP) that contains the target address of the branch. There are two sub-categories:

- **Near JMP Indirect and Near Call Indirect**

As previously mentioned, the target of an indirect COFI resides in the contents of either a register or memory location. Therefore, the processor must generate a packet that includes this target address to allow the decoder to determine the program flow.

- **Near RET**

When a CALL instruction executes, it pushes onto the stack the address of the next instruction following the CALL. Upon completion of the call procedure, the RET instruction is often used to pop the return address off of the call stack and redirect code flow back to the instruction following the CALL.

A RET instruction simply transfers program flow to the address it popped off the stack. Because a called procedure may change the return address on the stack before executing the RET instruction, debug software

can be misled if it assumes that code flow will return to the instruction following the last CALL. Therefore, even for near RET, a Target IP Packet may be sent.

#### — RET Compression

A special case is applied if the target of the RET is consistent with what would be expected from tracking the CALL stack. If it is assured that the decoder has seen the corresponding CALL (with “corresponding” defined as the CALL with matching stack depth), and the RET target is the instruction after that CALL, the RET target may be “compressed”. In this case, only a single TNT bit of “taken” is generated instead of a Target IP Packet. To ensure that the decoder will not be confused in cases of RET compression, only RETs that correspond to CALLs which have been seen since the last PSB packet may be compressed in a given logical processor. For details, see “Indirect Transfer Compression for Returns (RET)” in Section 33.4.2.2.

### 33.2.1.3 Far Transfer COFI

All operations that change the instruction pointer and are not near jumps are “far transfers”. This includes exceptions, interrupts, traps, TSX aborts, and instructions that do far transfers.

All far transfers will produce a Target IP (TIP) packet, which provides the destination IP address. For those far transfers that cannot be inferred from the binary source (e.g., asynchronous events such as exceptions and interrupts), the TIP will be preceded by a Flow Update packet (FUP), which provides the source IP address at which the event was taken. Table 33-23 indicates exactly which IP will be included in the FUP generated by a far transfer.

## 33.2.2 Software Trace Instrumentation with PTWRITE

PTWRITE provides a mechanism by which software can instrument the Intel PT trace. PTWRITE is a ring3-accessible instruction that can be passed to a register or memory variable, see “PTWRITE—Write Data to a Processor Trace Packet” in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B for details. The contents of that variable will be used as the payload for the PTW packet (see Table 33-40 “PTW Packet Definition”), inserted at the time of PTWRITE retirement, assuming PTWRITE is enabled and all other filtering conditions are met. Decode and analysis software will then be able to determine the meaning of the PTWRITE packet based on the IP of the associated PTWRITE instruction.

PTWRITE is enabled via IA32\_RTIT\_CTL.PTWEn[12] (see Table 33-6). Optionally, the user can use IA32\_RTIT\_CTL.FUPonPTW[5] to enable PTW packets to be followed by FUP packets containing the IP of the associated PTWRITE instruction. Support for PTWRITE is introduced in Intel Atom processors based on the Goldmont Plus microarchitecture.

### 33.2.3 Power Event Tracing

Power Event Trace is a capability that exposes core- and thread-level sleep state and power down transition information. When this capability is enabled, the trace will expose information about:

- Scenarios where software execution stops.
  - Due to sleep state entry, frequency change, or other powerdown.
  - Includes the IP, when in the tracing context.
- The requested and resolved hardware thread C-state.
  - Including indication of hardware autonomous C-state entry.
- The last and deepest core C-state achieved during a sleep session.
- The reason for C-state wake.

This information is in addition to the bus ratio (CBR) information provided by default after any powerdown, and the timing information (TSC, TMA, MTC, CYC) provided during or after a powerdown state.

Power Event Trace is enabled via IA32\_RTIT\_CTL.PwrEvtEn[4]. Support for Power Event Tracing is introduced in Intel Atom processors based on the Goldmont Plus microarchitecture.

### 33.2.4 Event Tracing

Event Trace is a capability that exposes details about the asynchronous events, when they are generated, and when their corresponding software event handler completes execution. These include:

- Interrupts, including NMI and SMI, including the interrupt vector when defined.
- Faults, exceptions including the fault vector.
  - Page faults additionally include the page fault address, when in context.
- Event handler returns, including IRET and RSM.
- VM exits and VM entries.<sup>1</sup>
  - VM exits include the values written to the “exit reason” and “exit qualification” VMCS fields.
- INIT and SIPI events.
- TSX aborts, including the abort status returned for the RTM instructions.
- Shutdown.

Additionally, it provides indication of the status of the Interrupt Flag (IF), to indicate when interrupts are masked.

Event Trace is enabled via IA32\_RTIT\_CTL.EventEn[31]. Event Trace information is conveyed in Control Flow Event (CFE) and Event Data (EVD) packets, as well as the legacy MODE.Exec packet. See Section 33.4.2 for packet details. Support for Event Trace is introduced in Intel® processors based on Gracemont microarchitecture.

### 33.2.5 Trace Filtering

Intel Processor Trace provides filtering capabilities, by which the debug/profile tool can control what code is traced.

#### 33.2.5.1 Filtering by Current Privilege Level (CPL)

Intel PT provides the ability to configure a logical processor to generate trace packets only when CPL = 0, when CPL > 0, or regardless of CPL.

CPL filtering ensures that no IPs or other architectural state information associated with the filtered CPL can be seen in the log. For example, if the processor is configured to trace only when CPL > 0, and software executes SYSCALL (changing the CPL to 0), the destination IP of the SYSCALL will be suppressed from the generated packet (see the discussion of TIP.PGD in Section 33.4.2.5).

It should be noted that CPL is always 0 in real-address mode and that CPL is always 3 in virtual-8086 mode. To trace code in these modes, filtering should be configured accordingly.

When software is executing in a non-enabled CPL, ContextEn is cleared. See Section 33.2.6.1 for details.

#### 33.2.5.2 Filtering by CR3

Intel PT supports a CR3-filtering mechanism by which the generation of packets containing architectural states can be enabled or disabled based on the value of CR3. A debugger can use CR3 filtering to trace only a single application without context switching the state of the RTIT MSRs. For the reconstruction of traces from software with multiple threads, debug software may wish to context-switch for the state of the RTIT MSRs (if the operating system does not provide context-switch support) to separate the output for the different threads (see Section 33.3.5, “Context Switch Consideration”).

To trace for only a single CR3 value, software can write that value to the IA32\_RTIT\_CR3\_MATCH MSR, and set IA32\_RTIT\_CTL.CR3Filter. When CR3 value does not match IA32\_RTIT\_CR3\_MATCH and IA32\_RTIT\_CTL.CR3Filter is 1, ContextEn is forced to 0, and packets containing architectural states will not be generated. Some other packets can be generated when ContextEn is 0; see Section 33.2.6.3 for details. When CR3 does match IA32\_RTIT\_CR3\_MATCH (or when IA32\_RTIT\_CTL.CR3Filter is 0), CR3 filtering does not force ContextEn to 0 (although it could be 0 due to other filters or modes).

---

1. Logging of VMX transitions depends on VMCS configuration, see Section 33.5.1.

CR3 matches IA32\_RTIT\_CR3\_MATCH if the two registers are identical for bits 63:12, or 63:5 when in PAE paging mode; the lower 5 bits of CR3 and IA32\_RTIT\_CR3\_MATCH are ignored. CR3 filtering is independent of the value of CR0.PG.

When CR3 filtering is in use, PIP packets may still be seen in the log if the processor is configured to trace when CPL = 0 (IA32\_RTIT\_CTL.OS = 1). If not, no PIP packets will be seen.

### 33.2.5.3 Filtering by IP

Trace packet generation with configurable filtering by IP is supported if CPUID.(EAX=14H, ECX=0):EBX[bit 2] = 1. Intel PT can be configured to enable the generation of packets containing architectural states only when the processor is executing code within certain IP ranges. If the IP is outside of these ranges, generation of some packets is blocked.

IP filtering is enabled using the ADDRn\_CFG fields in the IA32\_RTIT\_CTL MSR (Section 33.2.8.2), where the digit 'n' is a zero-based number that selects which address range is being configured. Each ADDRn\_CFG field configures the use of the register pair IA32\_RTIT\_ADDRn\_A and IA32\_RTIT\_ADDRn\_B (Section 33.2.8.5). IA32\_RTIT\_ADDRn\_A defines the base and IA32\_RTIT\_ADDRn\_B specifies the limit of the range in which tracing is enabled. Thus each range, referred to as the ADDRn range, is defined by [IA32\_RTIT\_ADDRn\_A, IA32\_RTIT\_ADDRn\_B]. There can be multiple such ranges, software can query CPUID (Section 33.3.1) for the number of ranges supported on a processor.

Default behavior (ADDRn\_CFG=0) defines no IP filter range, meaning FilterEn is always set. In this case code at any IP can be traced, though other filters, such as CR3 or CPL, could limit tracing. When ADDRn\_CFG is set to enable IP filtering (see Section 33.3.1), tracing will commence when a taken branch or event is seen whose target address is in the ADDRn range.

While inside a tracing region and with FilterEn is set, leaving the tracing region may only be detected once a taken branch or event with a target outside the range is retired. If an ADDRn range is entered or exited by executing the next sequential instruction, rather than by a control flow transfer, FilterEn may not toggle immediately. See Section 33.2.6.5 for more details on FilterEn.

Note that these address range base and limit values are inclusive, such that the range includes the first and last instruction whose first instruction byte is in the ADDRn range.

Depending upon processor implementation, IP filtering may be based on linear or effective address. This can cause different behavior between implementations if CSbase is not equal to zero or in real mode. See Section 33.3.1.1 for details. Software can query CPUID to determine filters are based on linear or effective address (Section 33.3.1).

Note that some packets, such as MTC (Section 33.3.7) and other timing packets, do not depend on FilterEn. For details on which packets depend on FilterEn, and hence are impacted by IP filtering, see Section 33.4.1.

### TraceStop

The ADDRn ranges can also be configured to cause tracing to be disabled upon entry to the specified region. This is intended for cases where unexpected code is executed, and the user wishes to immediately stop generating packets in order to avoid overwriting previously written packets.

The TraceStop mechanism works much the same way that IP filtering does, and uses the same address comparison logic. The TraceStop region base and limit values are programmed into one or more ADDRn ranges, but IA32\_RTIT\_CTL.ADDRn\_CFG is configured with the TraceStop encoding. Like FilterEn, TraceStop is detected when a taken branch or event lands in a TraceStop region.

Further, TraceStop requires that TriggerEn=1 at the beginning of the branch/event, and ContextEn=1 upon completion of the branch/event. When this happens, the CPU will set IA32\_RTIT\_STATUS.Stopped, thereby clearing TriggerEn and hence disabling packet generation. This may generate a TIP.PGD packet with the target IP of the branch or event that entered the TraceStop region. Finally, a TraceStop packet will be inserted, to indicate that the condition was hit.

If a TraceStop condition is encountered during buffer overflow (Section 33.3.8), it will not be dropped, but will instead be signaled once the overflow has resolved.

Note that a TraceStop event does not guarantee that all internally buffered packets are flushed out of internal buffers. To ensure that this has occurred, the user should clear TraceEn.

To resume tracing after a TraceStop event, the user must first disable Intel PT by clearing IA32\_RTIT\_CTL.TraceEn before the IA32\_RTIT\_STATUS.Stopped bit can be cleared. At this point Intel PT can be reconfigured, and tracing resumed.

Note that the IA32\_RTIT\_STATUS.Stopped bit can also be set using the ToPA STOP bit. See Section 33.2.7.2.

### IP Filtering Example

The following table gives an example of IP filtering behavior. Assume that IA32\_RTIT\_ADDRn\_A = the IP of RangeBase, and that IA32\_RTIT\_ADDRn\_B = the IP of RangeLimit, while IA32\_RTIT\_CTL.ADDRn\_CFG = 0x1 (enable ADDRn range as a FilterEn range).

**Table 33-2. IP Filtering Packet Example**

| Code Flow                                                                                                                                                                                                | Packets                                               |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|
| <pre> Bar:     jmp RangeBase // jump into filter range RangeBase:     jcc Foo // not taken     add eax, 1 Foo:     jmp RangeLimit+1 // jump out of filter range RangeLimit:     nop     jcc Bar   </pre> | TIP.PGE(RangeBase)<br>TNT(0)<br>TIP.PGD(RangeLimit+1) |

### IP Filtering and TraceStop

It is possible for the user to configure IP filter range(s) and TraceStop range(s) that overlap. In this case, code executing in the non-overlapping portion of either range will behave as would be expected from that range. Code executing in the overlapping range will get TraceStop behavior.

## 33.2.6 Packet Generation Enable Controls

Intel Processor Trace includes a variety of controls that determine whether a packet is generated. In general, most packets are sent only if Packet Enable (**PacketEn**) is set. PacketEn is an internal state maintained in hardware in response to software configurable enable controls, PacketEn is not visible to software directly. The relationship of PacketEn to the software-visible controls in the configuration MSRs is described in this section.

### 33.2.6.1 Packet Enable (PacketEn)

When PacketEn is set, the processor is in the mode that Intel PT is monitoring. PacketEn is composed of other states according to this relationship:

$$\text{PacketEn} := \text{TriggerEn} \text{ AND } \text{ContextEn} \text{ AND } \text{FilterEn} \text{ AND } \text{BranchEn}$$

These constituent controls are detailed in the following subsections.

PacketEn ultimately determines when the processor is tracing. When PacketEn is set, all control flow packets are enabled. When PacketEn is clear, no control flow packets are generated, though other packets (timing and book-keeping packets) may still be sent. See Section 33.2.7 for details of PacketEn and packet generation.

Note that, on processors that do not support IP filtering (i.e., CPUID.(EAX=14H, ECX=0):EBX[bit 2] = 0), FilterEn is treated as always set.

### 33.2.6.2 Trigger Enable (TriggerEn)

Trigger Enable (**TriggerEn**) is the primary indicator that trace packet generation is active. TriggerEn is set when IA32\_RTIT\_CTL.TraceEn is set, and cleared by any of the following conditions:

- TraceEn is cleared by software.
- A TraceStop condition is encountered and IA32\_RTIT\_STATUS.Stopped is set.
- IA32\_RTIT\_STATUS.Error is set due to an operational error (see Section 33.3.10).

Software can discover the current TriggerEn value by reading the IA32\_RTIT\_STATUS.TriggerEn bit. When TriggerEn is clear, tracing is inactive and no packets are generated.

### 33.2.6.3 Context Enable (ContextEn)

Context Enable (**ContextEn**) indicates whether the processor is in the state or mode that software configured hardware to trace. For example, if execution with CPL = 0 code is not being traced (IA32\_RTIT\_CTL.OS = 0), then ContextEn will be 0 when the processor is in CPL0.

Software can discover the current ContextEn value by reading the IA32\_RTIT\_STATUS.ContextEn bit. ContextEn is defined as follows:

```
ContextEn = !((IA32_RTIT_CTL.OS = 0 AND CPL = 0) OR
 (IA32_RTIT_CTL.USER = 0 AND CPL > 0) OR (IS_IN_A_PRODUCTION_ENCLAVE1) OR
 (IA32_RTIT_CTL.CR3Filter = 1 AND IA32_RTIT_CR3_MATCH does not match CR3)
```

If the clearing of ContextEn causes PacketEn to be cleared, a Packet Generation Disable (TIP.PGD) packet is generated, but its IP payload is suppressed. If the setting of ContextEn causes PacketEn to be set, a Packet Generation Enable (TIP.PGE) packet is generated.

When ContextEn is 0, control flow packets (TNT, FUP, TIP.\* , MODE.\* ) are not generated, and no Linear Instruction Pointers (LIPs) are exposed. However, some packets, such as MTC and PSB (see Section 33.4.2.16 and Section 33.4.2.17), may still be generated while ContextEn is 0. For details of which packets are generated only when ContextEn is set, see Section 33.4.1.

The processor does not update ContextEn when TriggerEn = 0.

The value of ContextEn will toggle only when TriggerEn = 1.

### 33.2.6.4 Branch Enable (BranchEn)

This value is based purely on the IA32\_RTIT\_CTL.BranchEn value. If **BranchEn** is not set, then relevant COFI packets (TNT, TIP\*, FUP, MODE.\* ) are suppressed. Other packets related to timing (TSC, TMA, MTC, CYC), as well as PSB, will be generated normally regardless. Further, PIP and VMCS continue to be generated, as indicators of what software is running.

### 33.2.6.5 Filter Enable (FilterEn)

Filter Enable indicates that the Instruction Pointer (IP) is within the range of IPs that Intel PT is configured to watch. Software can get the state of Filter Enable by a RDMSR of IA32\_RTIT\_STATUS.FilterEn. For details on configuration and use of IP filtering, see Section 33.2.5.3.

On clearing of FilterEn that also clears PacketEn, a Packet Generation Disable (TIP.PGD) will be generated, but unlike the ContextEn case, the IP payload may not be suppressed. For direct, unconditional branches, as well as for indirect branches (including RETs), the PGD generated by leaving the tracing region and clearing FilterEn will contain the target IP. This means that IPs from outside the configured range can be exposed in the trace, as long as they are within context.

When FilterEn is 0, control flow packets are not generated (e.g., TNT, TIP). However, some packets, such as PIP, MTC, and PSB, may still be generated while FilterEn is clear. For details on packet enable dependencies, see Section 33.4.1.

---

1. Trace packets generation is disabled in a production enclave, see Section 33.2.9.5. See the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3D, about differences between a production enclave and a debug enclave.

After TraceEn is set, FilterEn is set to 1 at all times if there is no IP filter range configured by software ( $\text{IA32\_RTIT\_CTL.ADDRn\_CFG} \neq 1$ , for all n), or if the processor does not support IP filtering (i.e.,  $\text{CPUID.(EAX=14H, ECX=0):EBX[bit 2]} = 0$ ). FilterEn will toggle only when TraceEn=1 and ContextEn=1, and when at least one range is configured for IP filtering.

### 33.2.7 Trace Output

Intel PT output should be viewed independently from trace content and filtering mechanisms. The options available for trace output can vary across processor generations and platforms.

Trace output is written out using one of the following output schemes, as configured by the ToPA and FabricEn bit fields of IA32\_RTIT\_CTL (see Section 33.2.8.2):

- A single, contiguous region of physical address space.
- A collection of variable-sized regions of physical memory. These regions are linked together by tables of pointers to those regions, referred to as Table of Physical Addresses (**ToPA**). The trace output stores bypass the caches and the TLBs, but are not serializing. This is intended to minimize the performance impact of the output.
- A platform-specific trace transport subsystem.

Regardless of the output scheme chosen, Intel PT stores bypass the processor caches by default. This ensures that they don't consume precious cache space, but they do not have the serializing aspects associated with un-cacheable (UC) stores. Software should avoid using MTRRs to mark any portion of the Intel PT output region as UC, as this may override the behavior described above and force Intel PT stores to UC, thereby incurring severe performance impact.

There is no guarantee that a packet will be written to memory or other trace endpoint after some fixed number of cycles after a packet-producing instruction executes. The only way to assure that all packets generated have reached their endpoint is to clear TraceEn and follow that with a store, fence, or serializing instruction; doing so ensures that all buffered packets are flushed out of the processor.

#### 33.2.7.1 Single Range Output

When IA32\_RTIT\_CTL.ToPA and IA32\_RTIT\_CTL.FabricEn bits are clear, trace packet output is sent to a single, contiguous memory (or MMIO if DRAM is not available) range defined by a base address in IA32\_RTIT\_OUTPUT\_BASE (Section 33.2.8.7) and mask value in IA32\_RTIT\_OUTPUT\_MASK\_PTRS (Section 33.2.8.8). The current write pointer in this range is also stored in IA32\_RTIT\_OUTPUT\_MASK\_PTRS. This output range is circular, meaning that when the writes wrap around the end of the buffer they begin again at the base address.

This output method is best suited for cases where Intel PT output is either:

- Configured to be directed to a sufficiently large contiguous region of DRAM.
- Configured to go to an MMIO debug port, in order to route Intel PT output to a platform-specific trace endpoint (e.g., JTAG). In this scenario, a specific range of addresses is written in a circular manner, and SoC will intercept these writes and direct them to the proper device. Repeated writes to the same address do not overwrite each other, but are accumulated by the debugger, and hence no data is lost by the circular nature of the buffer.

The processor will determine the address to which to write the next trace packet output byte as follows:

```

OutputBase[63:0] := IA32_RTIT_OUTPUT_BASE[63:0]
OutputMask[63:0] := ZeroExtend64(IA32_RTIT_OUTPUT_MASK_PTRS[31:0])
OutputOffset[63:0] := ZeroExtend64(IA32_RTIT_OUTPUT_MASK_PTRS[63:32])
trace_store_phys_addr := (OutputBase & ~OutputMask) + (OutputOffset & OutputMask)

```

## Single-Range Output Errors

If the output base and mask are not properly configured by software, an operational error (see Section 33.3.10) will be signaled, and tracing disabled. Error scenarios with single-range output are:

- Mask value is non-contiguous.  
IA32\_RTIT\_OUTPUT\_MASK\_PTRS.MaskOrTablePointer value has a 0 in a less significant bit position than the most significant bit containing a 1.
- Base address and Mask are mis-aligned, and have overlapping bits set.  
IA32\_RTIT\_OUTPUT\_BASE && IA32\_RTIT\_OUTPUT\_MASK\_PTRS[31:0] > 0.
- Illegal Output Offset  
IA32\_RTIT\_OUTPUT\_MASK\_PTRS.OutputOffset is greater than the mask value IA32\_RTIT\_OUTPUT\_MASK\_PTRS[31:0].

Also note that errors can be signaled due to trace packet output overlapping with restricted memory, see Section 33.2.7.4.

### 33.2.7.2 Table of Physical Addresses (ToPA)

When IA32\_RTIT\_CTL.ToPA is set and IA32\_RTIT\_CTL.FabricEn is clear, the ToPA output mechanism is utilized. The ToPA mechanism uses a linked list of tables; see Figure 33-1 for an illustrative example. Each entry in the table contains some attribute bits, a pointer to an output region, and the size of the region. The last entry in the table may hold a pointer to the next table. This pointer can either point to the top of the current table (for circular array) or to the base of another table. The table size is not fixed, since the link to the next table can exist at any entry.

The processor treats the various output regions referenced by the ToPA table(s) as a unified buffer. This means that a single packet may span the boundary between one output region and the next.

The ToPA mechanism is controlled by three values maintained by the processor:

- **proc\_trace\_table\_base.**  
This is the physical address of the base of the current ToPA table. When tracing is enabled, the processor loads this value from the IA32\_RTIT\_OUTPUT\_BASE MSR. While tracing is enabled, the processor updates the IA32\_RTIT\_OUTPUT\_BASE MSR with changes to proc\_trace\_table\_base, but these updates may not be synchronous to software execution. When tracing is disabled, the processor ensures that the MSR contains the latest value of proc\_trace\_table\_base.
- **proc\_trace\_table\_offset.**  
This indicates the entry of the current table that is currently in use. (This entry contains the address of the current output region.) When tracing is enabled, the processor loads the value from bits 31:7 (MaskOrTableOffset) of the IA32\_RTIT\_OUTPUT\_MASK\_PTRS into bits 27:3 of proc\_trace\_table\_offset. While tracing is enabled, the processor updates IA32\_RTIT\_OUTPUT\_MASK\_PTRS.MaskOrTableOffset with changes to proc\_trace\_table\_offset, but these updates may not be synchronous to software execution. When tracing is disabled, the processor ensures that the MSR contains the latest value of proc\_trace\_table\_offset.
- **proc\_trace\_output\_offset.**  
This is a pointer into the current output region and indicates the location of the next write. When tracing is enabled, the processor loads this value from bits 63:32 (OutputOffset) of the IA32\_RTIT\_OUTPUT\_MASK\_PTRS. While tracing is enabled, the processor updates IA32\_RTIT\_OUTPUT\_MASK\_PTRS.OutputOffset with changes to proc\_trace\_output\_offset, but these updates may not be synchronous to software execution. When tracing is disabled, the processor ensures that the MSR contains the latest value of proc\_trace\_output\_offset.

Figure 33-1 provides an illustration (not to scale) of the table and associated pointers.

**Figure 33-1. ToPA Memory Illustration**

With the ToPA mechanism, the processor writes packets to the current output region (identified by `proc_trace_table_base` and the `proc_trace_table_offset`). The offset within that region to which the next byte will be written is identified by `proc_trace_output_offset`. When that region is filled with packet output (thus `proc_trace_output_offset = RegionSize-1`), `proc_trace_table_offset` is moved to the next ToPA entry, `proc_trace_output_offset` is set to 0, and packet writes begin filling the new output region specified by `proc_trace_table_offset`.

As packets are written out, each store derives its physical address as follows:

```
trace_store_phys_addr := Base address from current ToPA table entry +
proc_trace_output_offset
```

Eventually, the regions represented by all entries in the table may become full, and the final entry of the table is reached. An entry can be identified as the final entry because it has either the END or STOP attribute. The END attribute indicates that the address in the entry does not point to another output region, but rather to another ToPA table. The STOP attribute indicates that tracing will be disabled once the corresponding region is filled. See Table 33-3 and the section that follows for details on STOP.

When an END entry is reached, the processor loads `proc_trace_table_base` with the base address held in this END entry, thereby moving the current table pointer to this new table. The `proc_trace_table_offset` is reset to 0, as is the `proc_trace_output_offset`, and packet writes will resume at the base address indicated in the first entry.

If the table has no STOP or END entry, and trace-packet generation remains enabled, eventually the maximum table size will be reached (`proc_trace_table_offset = OFFFFFFF8H`). In this case, the `proc_trace_table_offset` and `proc_trace_output_offset` are reset to 0 (wrapping back to the beginning of the current table) once the last output region is filled.

It is important to note that processor updates to the IA32\_RTIT\_OUTPUT\_BASE and IA32\_RTIT\_OUTPUT\_MASK\_PTRS MSRs are asynchronous to instruction execution. Thus, reads of these MSRs while Intel PT is enabled may return stale values. Like all IA32\_RTIT\_\* MSRs, the values of these MSRs should not be trusted or saved unless trace packet generation is first disabled by clearing IA32\_RTIT\_CTL.TraceEn. This ensures that the output MSR values account for all packets generated to that point, after which the processor will cease updating the output MSR values until tracing resumes.<sup>1</sup>

The processor may cache internally any number of entries from the current table or from tables that it references (directly or indirectly). If tracing is enabled, the processor may ignore or delay detection of modifications to these tables. To ensure that table changes are detected by the processor in a predictable manner, software should clear TraceEn before modifying the current table (or tables that it references) and only then re-enable packet generation.

### Single Output Region ToPA Implementation

The first processor generation to implement Intel PT supports only ToPA configurations with a single ToPA entry followed by an END entry that points back to the first entry (creating one circular output buffer). Such processors enumerate CPUID.(EAX=14H,ECX=0):ECX.MENTRY[bit 1] = 0 and CPUID.(EAX=14H,ECX=0):ECX.TOPAOUT[bit 0] = 1.

If CPUID.(EAX=14H,ECX=0):ECX.MENTRY[bit 1] = 0, ToPA tables can hold only one output entry, which must be followed by an END=1 entry which points back to the base of the table. Hence only one contiguous block can be used as output.

The lone output entry can have INT or STOP set, but nonetheless must be followed by an END entry as described above. Note that, if INT=1, the PMI will actually be delivered before the region is filled.

### ToPA Table Entry Format

The format of ToPA table entries is shown in Figure 33-2. The size of the address field is determined by the processor's physical-address width (MAXPHYADDR) in bits, as reported in CPUID.80000008H:EAX[7:0].

Figure 33-2. Layout of ToPA Table Entry

Table 33-3 describes the details of the ToPA table entry fields. If reserved bits are set to 1, an error is signaled.

Table 33-3. ToPA Table Entry Fields

| ToPA Entry Field                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Output Region Base Physical Address | If END=0, this is the base physical address of the output region specified by this entry. Note that all regions must be aligned based on their size. Thus a 2M region must have bits 20:12 clear. If the region is not properly aligned, an operational error will be signaled when the entry is reached.<br>If END=1, this is the 4K-aligned base physical address of the next ToPA table (which may be the base of the current table, or the first table in the linked list if a circular buffer is desired). If the processor supports only a single ToPA output region (see above), this address must be the value currently in the IA32_RTIT_OUTPUT_BASE MSR. |

1. Although WRMSR is a serializing instruction, the execution of WRMSR that forces packet writes by clearing TraceEn does not itself cause these writes to be globally observed.

**Table 33-3. ToPA Table Entry Fields (Contd.)**

| ToPA Entry Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Size             | Indicates the size of the associated output region. Encodings are:<br>0: 4K, 1: 8K, 2: 16K, 3: 32K, 4: 64K, 5: 128K, 6: 256K, 7: 512K,<br>8: 1M, 9: 2M, 10: 4M, 11: 8M, 12: 16M, 13: 32M, 14: 64M, 15: 128M<br>This field is ignored if END=1.                                                                                                                                                                                                      |
| STOP             | When the output region indicated by this entry is filled, software should disable packet generation. This will be accomplished by setting IA32_RTIT_STATUS.Stopped, which clears TriggerEn. This bit must be 0 if END=1; otherwise it is treated as reserved bit violation (see ToPA Errors).                                                                                                                                                       |
| INT              | When the output region indicated by this entry is filled, signal Perfmon LVT interrupt.<br>Note that if both INT and STOP are set in the same entry, the STOP will happen before the INT. Thus the interrupt handler should expect that the IA32_RTIT_STATUS.Stopped bit will be set, and will need to be reset before tracing can be resumed.<br>This bit must be 0 if END=1; otherwise it is treated as reserved bit violation (see ToPA Errors). |
| END              | If set, indicates that this is an END entry, and thus the address field points to a table base rather than an output region base.<br>If END=1, INT and STOP must be set to 0; otherwise it is treated as reserved bit violation (see ToPA Errors). The Size field is ignored in this case.<br>If the processor supports only a single ToPA output region (see above), END must be set in the second table entry.                                    |

### ToPA STOP

Each ToPA entry has a STOP bit. If this bit is set, the processor will set the IA32\_RTIT\_STATUS.Stopped bit when the corresponding trace output region is filled. This will clear TriggerEn and thereby cease packet generation. See Section 33.2.8.4 for details on IA32\_RTIT\_STATUS.Stopped. This sequence is known as “ToPA Stop”.

No TIP.PGD packet will be seen in the output when the ToPA stop occurs, since the disable happens only when the region is already full. When this occurs, output ceases after the last byte of the region is filled, which may mean that a packet is cut off in the middle. Any packets remaining in internal buffers are lost and cannot be recovered.

When ToPA stop occurs, the IA32\_RTIT\_OUTPUT\_BASE MSR will hold the base address of the table whose entry had STOP=1. IA32\_RTIT\_OUTPUT\_MASK\_PTRS.MaskOrTableOffset will hold the index value for that entry, and the IA32\_RTIT\_OUTPUT\_MASK\_PTRS.OutputOffset should be set to the size of the region minus one.

Note that this means the offset pointer is pointing to the next byte after the end of the region, a configuration that would produce an operational error if the configuration remained when tracing is re-enabled with IA32\_RTIT\_STATUS.Stopped cleared.

### ToPA PMI

Each ToPA entry has an INT bit. If this bit is set, the processor will signal a performance-monitoring interrupt (PMI) when the corresponding trace output region is filled. This interrupt is not precise, and it is thus likely that writes to the next region will occur by the time the interrupt is taken.

The following steps should be taken to configure this interrupt:

1. Enable PMI via the LVT Performance Monitor register (at MMIO offset 340H in xAPIC mode; via MSR 834H in x2APIC mode). See the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3B, for more details on this register. For ToPA PMI, set all fields to 0, save for the interrupt vector, which can be selected by software.
2. Set up an interrupt handler to service the interrupt vector that a ToPA PMI can raise.
3. Set the interrupt flag by executing STI.
4. Set the INT bit in the ToPA entry of interest and enable packet generation, using the ToPA output option. Thus, TraceEn=ToPA=1 in the IA32\_RTIT\_CTL MSR.

Once the INT region has been filled with packet output data, the interrupt will be signaled. This PMI can be distinguished from others by checking bit 55 (Trace\_ToPA\_PMI) of the IA32\_PERF\_GLOBAL\_STATUS MSR (MSR 38EH). Once the ToPA PMI handler has serviced the relevant buffer, writing 1 to bit 55 of the MSR at 390H (IA32\_GLOBAL\_STATUS\_RESET) clears IA32\_PERF\_GLOBAL\_STATUS.Trace\_ToPA\_PMI.

Intel PT is not frozen on PMI, and thus the interrupt handler will be traced (though filtering can prevent this). The Freeze\_Perfmon\_on\_PMI and Freeze\_LBRs\_on\_PMI settings in IA32\_DEBUGCTL will be applied on ToPA PMI just as on other PMIs, and hence Perfmon counters are frozen.

Assuming the PMI handler wishes to read any buffered packets for persistent output, or wishes to modify any Intel PT MSRs, software should first disable packet generation by clearing TraceEn. This ensures that all buffered packets are written to memory and avoids tracing of the PMI handler. The configuration MSRs can then be used to determine where tracing has stopped. If packet generation is disabled by the handler, it should then be manually re-enabled before the IRET if continued tracing is desired.

In rare cases, it may be possible to trigger a second ToPA PMI before the first is handled. This can happen if another ToPA region with INT=1 is filled before, or shortly after, the first PMI is taken, perhaps due to EFLAGS.IF being cleared for an extended period of time. This can manifest in two ways: either the second PMI is triggered before the first is taken, and hence only one PMI is taken, or the second is triggered after the first is taken, and thus will be taken when the handler for the first completes. Software can minimize the likelihood of the second case by clearing TraceEn at the beginning of the PMI handler. Further, it can detect such cases by then checking the Interrupt Request Register (IRR) for PMI pending, and checking the ToPA table base and off-set pointers (in IA32\_RTIT\_OUTPUT\_BASE and IA32\_RTIT\_OUTPUT\_MASK\_PTRS) to see if multiple entries with INT=1 have been filled.

## PMI Preservation

In some cases a ToPA PMI may be taken after completion of an XSAVES instruction that saves Intel PT state, and in such cases any modification of Intel PT MSRs within the PMI handler will not persist when the saved Intel PT context is later restored with XRSTORS. To account for such a scenario, the PMI Preservation feature has been added. Support for this feature is indicated by CPUID.(EAX=14H, ECX=0):EBX[bit 6].

When IA32\_RTIT\_CTL.InjectPsbPmiOnEnable[56] = 1, PMI preservation is enabled. When a ToPA region with INT=1 is filled, a PMI is pended and the new IA32\_RTIT\_STATUS.PendToPAPMI[7] is set to 1. If this bit is set when Intel PT is enabled, such that IA32\_RTIT\_CTL.TraceEn[0] transitions from 0 to 1, a ToPA PMI is pended. This behavior ensures that any ToPA PMI that is pended during XSAVES, and hence can't be properly handled, will be re-pended when the saved PT state is restored.

When this feature is enabled, the PMI handler should take the following actions:

1. Ignore ToPA PMIs that are taken when TraceEn = 0. This indicates that the PMI was pended during Intel PT disable, and the PendToPAPMI flag will ensure that the PMI is re-pended once Intel PT is re-enabled in the same context. For this reason, the PendToPAPMI bit should be left set to 1.
2. If TraceEn=1 and the PMI can be properly handled, clear the new PendTopaPMI bit. This will ensure that additional, spurious ToPA PMIs are not taken. It is required that PendToPAPMI is cleared before the PMI LVT mask is cleared in the APIC, and before any clearing of either LBRs\_FROZEN or COUNTERS\_FROZEN in IA32\_PERF\_GLOBAL\_STATUS.

## ToPA PMI and Single Output Region ToPA Implementation

A processor that supports only a single ToPA output region implementation (such that only one output region is supported; see above) will attempt to signal a ToPA PMI interrupt before the output wraps and overwrites the top of the buffer. To support this functionality, the PMI handler should disable packet generation as soon as possible.

Due to PMI skid, it is possible that, in rare cases, the wrap will have occurred before the PMI is delivered. Software can avoid this by setting the STOP bit in the ToPA entry (see Table 33-3); this will disable tracing once the region is filled, and no wrap will occur. This approach has the downside of disabling packet generation so that some of the instructions that led up to the PMI will not be traced. If the PMI skid is significant enough to cause the region to fill and tracing to be disabled, the PMI handler will need to clear the IA32\_RTIT\_STATUS.Stopped indication before tracing can resume.

## ToPA PMI and XSAVES/XRSTORS State Handling

In some cases the ToPA PMI may be taken after completion of an XSAVES instruction that switches Intel PT state, and in such cases any modification of Intel PT MSRs within the PMI handler will not persist when the saved Intel PT context is later restored with XRSTORS. To account for such a scenario, it is recommended that the Intel PT output configuration be modified by altering the ToPA tables themselves, rather than the Intel PT output MSRs. On processors that support PMI preservation (CPUID.(EAX=14H, ECX=0):EBX[bit 6] = 1), setting IA32\_RTIT\_CTL.InjectPsb-PmiOnEnable[56] = 1 will ensure that a PMI that is pending at the time PT is disabled will be recorded by setting IA32\_RTIT\_STATUS.PendTopaPMI[7] = 1. A PMI will then be pended when the saved PT context is later restored.

Table 33-4 depicts a recommended PMI handler algorithm for managing multi-region ToPA output and handling ToPA PMIs that may arrive between XSAVES and XRSTORS, if PMI preservation is not in use. This algorithm is flexible to allow software to choose between adding entries to the current ToPA table, adding a new ToPA table, or using the current ToPA table as a circular buffer. It assumes that the ToPA entry that triggers the PMI is not the last entry in the table, which is the recommended treatment.

**Table 33-4. Algorithm to Manage Intel PT ToPA PMI and XSAVES/XRSTORS**

| Pseudo Code Flow                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <pre> IF (IA32_PERF_GLOBAL_STATUS.ToPA)     Save IA32_RTIT_CTL value;     IF ( IA32_RTIT_CTL.TraceEN )         Disable Intel PT by clearing TraceEn;     FI;     IF ( there is space available to grow the current ToPA table )         Add one or more ToPA entries after the last entry in the ToPA table;         Point new ToPA entry address field(s) to new output region base(s);     ELSE         Modify an upcoming ToPA entry in the current table to have END=1;         IF (output should transition to a new ToPA table)             Point the address of the "END=1" entry of the current table to the new table base;         ELSE             /* Continue to use the current ToPA table, make a circular. */             Point the address of the "END=1" entry to the base of the current table;             Modify the ToPA entry address fields for filled output regions to point to new, unused output regions;             /* Filled regions are those with index in the range of 0 to (IA32_RTIT_MASK_PTRS.MaskOrTableOffset -1). */         FI;     FI;     Restore saved IA32_RTIT_CTL.value; FI;</pre> |

## ToPA Errors

When a malformed ToPA entry is found, an **operational error** results (see Section 33.3.10). A malformed entry can be any of the following:

1. **ToPA entry reserved bit violation.**

This describes cases where a bit marked as reserved in Section 33.2.7.2 above is set to 1.

2. **ToPA alignment violation.**

This includes cases where illegal ToPA entry base address bits are set to 1:

- a. ToPA table base address is not 4KB-aligned. The table base can be from a WRMSR to IA32\_RTIT\_OUTPUT\_BASE, or from a ToPA entry with END=1.
- b. ToPA entry base address is not aligned to the ToPA entry size (e.g., a 2MB region with base address[20:12] not equal to 0), for ToPA entries with END=0.
- c. ToPA entry base address sets upper physical address bits not supported by the processor.

### 3. Illegal ToPA Output Offset.

IA32\_RTIT\_OUTPUT\_MASK\_PTRS.OutputOffset is greater than or equal to the size of the current ToPA output region size.

### 4. ToPA rules violations.

These are similar to ToPA entry reserved bit violations; they are cases when a ToPA entry is encountered with illegal field combinations. They include the following:

- a. Setting the STOP or INT bit on an entry with END=1.
- b. Setting the END bit in entry 0 of a ToPA table.
- c. On processors that support only a single ToPA entry (see above), two additional illegal settings apply:
  - i) ToPA table entry 1 with END=0.
  - ii) ToPA table entry 1 with base address not matching the table base.

In all cases, the error will be logged by setting IA32\_RTIT\_STATUS.Error, thereby disabling tracing when the problematic ToPA entry is reached (when proc\_trace\_table\_offset points to the entry containing the error). Any packet bytes that are internally buffered when the error is detected may be lost.

Note that operational errors may also be signaled due to attempts to access restricted memory. See Section 33.2.7.4 for details.

A tracing software have a range of flexibility using ToPA to manage the interaction of Intel PT with application buffers, see Section 33.4.2.26.

### 33.2.7.3 Trace Transport Subsystem

When IA32\_RTIT\_CTL.FabricEn is set, the IA32\_RTIT\_CTL.ToPA bit is ignored, and trace output is written to the trace transport subsystem. The endpoints of this transport are platform-specific, and details of configuration options should refer to the specific platform documentation. The FabricEn bit is available to be set if CPUID(EAX=14H,ECX=0):EBX[bit 3] = 1.

### 33.2.7.4 Restricted Memory Access

Packet output cannot be directed to any regions of memory that are restricted by the platform. In particular, all memory accesses on behalf of packet output are checked against the SMRR regions. If there is any overlap with these regions, trace data collection will not function properly. Exact processor behavior is implementation-dependent; Table 33-5 summarizes several scenarios.

**Table 33-5. Behavior on Restricted Memory Access**

| Scenario                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ToPA output region overlaps with SMRR | Stores to the restricted memory region will be dropped, and that packet data will be lost. Any attempt to read from that restricted region will return all 1s. The processor also may signal an error (Section 33.3.10) and disable tracing when the output pointer reaches the restricted region. If packet generation remains enabled, then packet output may continue once stores are no longer directed to restricted memory (on wrap, or if the output region is larger than the restricted memory region). |
| ToPA table overlaps with SMRR         | The processor will signal an error (Section 33.3.10) and disable tracing when the ToPA write pointer (IA32_RTIT_OUTPUT_BASE + proc_trace_table_offset) enters the restricted region.                                                                                                                                                                                                                                                                                                                             |

It should also be noted that packet output should not be routed to the 4KB APIC MMIO region, as defined by the IA32\_APIC\_BASE MSR. For details about the APIC, refer to the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A. No error is signaled for this case.

### Modifications to Restricted Memory Regions

It is recommended that software disable packet generation before modifying the SMRRs to change the scope of the SMRR regions. This is because the processor reserves the right to cache any number of ToPA table entries internally, after checking them against restricted memory ranges. Once cached, the entries will not be checked again, meaning one could potentially route packet output to a newly restricted region. Software can ensure that any cached entries are written to memory by clearing IA32\_RTIT\_CTL.TraceEn.

## 33.2.8 Enabling and Configuration MSRs

### 33.2.8.1 General Considerations

Trace packet generation is enabled and configured by a collection of model-specific registers (MSRs), which are detailed below. Some notes on the configuration MSR behavior:

- If Intel Processor Trace is not supported by the processor (see Section 33.3.1), RDMSR or WRMSR of the IA32\_RTIT\_\* MSRs will cause #GP.
- A WRMSR to any of the IA32\_RTIT\_\* configuration MSRs while packet generation is enabled (IA32\_RTIT\_CTL.TraceEn=1) will generate a #GP exception. Packet generation must be disabled before the configuration MSRs can be changed.

Note: Software may write the same value back to IA32\_RTIT\_CTL without #GP, even if TraceEn=1.

- All configuration MSRs for Intel PT are duplicated per logical processor
- For each configuration MSR, any MSR write that attempts to change bits marked reserved, or utilize encodings marked reserved, will cause a #GP fault.
- All configuration MSRs for Intel PT are cleared on a warm or cold RESET.
  - If CPUID.(EAX=14H, ECX=0):EBX[bit 2] = 1, only the TraceEn bit is cleared on warm RESET; though this may have the impact of clearing other bits in IA32\_RTIT\_STATUS. Other MSR values of the trace configuration MSRs are preserved on warm RESET.
- The semantics of MSR writes to trace configuration MSRs in this chapter generally apply to explicit WRMSR to these registers, using VMexit or VM entry MSR load list to these MSRs, XRSTORS with requested feature bit map including XSAVE map component of state\_8 (corresponding to IA32\_XSS[bit 8]), and the write to IA32\_RTIT\_CTL.TraceEn by XSAVES (Section 33.3.5.2).

### 33.2.8.2 IA32\_RTIT\_CTL MSR

IA32\_RTIT\_CTL, at address 570H, is the primary enable and control MSR for trace packet generation. Bit positions are listed in Table 33-6.

**Table 33-6. IA32\_RTIT\_CTL MSR**

| Position | Bit Name | At Reset | Bit Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------|----------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0        | TraceEn  | 0        | If 1, enables tracing; else tracing is disabled.<br>When this bit transitions from 1 to 0, all buffered packets are flushed out of internal buffers. A further store, fence, or architecturally serializing instruction may be required to ensure that packet data can be observed at the trace endpoint. See Section 33.2.8.3 for details of enabling and disabling packet generation.<br>Note that the processor will clear this bit on #SMI (Section 33.2.9.3) and warm reset. Other MSR bits of IA32_RTIT_CTL (and other trace configuration MSRs) are not impacted by these events. |
| 1        | CYCEn    | 0        | 0: Disables CYC Packet (see Section 33.4.2.14).<br>1: Enables CYC Packet.<br>This bit is reserved if CPUID.(EAX=14H, ECX=0):EBX[bit 1] = 0.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 2        | OS       | 0        | 0: Packet generation is disabled when CPL = 0.<br>1: Packet generation may be enabled when CPL = 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| 27:24           | PSBFreq         | 0               | Indicates the frequency of PSB packets. PSB packet frequency is based on the number of Intel PT packet bytes output, so this field allows the user to determine the increment of IA32_IA32_RTIT_STATUS.PacketByteCnt that should cause a PSB to be generated. Note that PSB insertion is not precise, but the average output bytes per PSB should approximate the SW selected period. The following Encodings are defined:<br>0: 2K, 1: 4K, 2: 8K, 3: 16K, 4: 32K, 5: 64K, 6: 128K, 7: 256K,<br>8: 512K, 9: 1M, 10: 2M, 11: 4M, 12: 8M, 13: 16M, 14: 32M, 15: 64M<br>Software must use CPUID to query the supported encodings in the processor, see Section 33.3.1. Use of unsupported encodings will result in a #GP fault. This field is reserved if CPUID.(EAX=14H, ECX=0):EBX[bit 1] = 0. |

### 33.2.8.3 Enabling and Disabling Packet Generation with TraceEn

When TraceEn transitions from 0 to 1, Intel Processor Trace is enabled, and a series of packets may be generated. These packets help ensure that the decoder is aware of the state of the processor when the trace begins, and that it can keep track of any timing or state changes that may have occurred while packet generation was disabled. A full PSB+ (see Section 33.4.2.17) will be generated if IA32\_RTIT\_STATUS.PacketByteCnt=0, and may be generated in other cases as well. Otherwise, timing packets will be generated, including TSC, TMA, and CBR (see Section 33.4.1.1).

In addition to the packets discussed above, if and when PacketEn (Section 33.2.6.1) transitions from 0 to 1 (which may happen immediately, depending on filtering settings), a TIP.PGE packet (Section 33.4.2.3) will be generated.

When TraceEn is set, the processor may read ToPA entries from memory and cache them internally. For this reason, software should disable packet generation before making modifications to the ToPA tables (or changing the config-

uration of restricted memory regions). See Section 33.7 for more details of packets that may be generated with modifications to TraceEn.

### Disabling Packet Generation

Clearing TraceEn causes any packet data buffered within the logical processor to be flushed out, after which the output MSRs (IA32\_RTIT\_OUTPUT\_BASE and IA32\_RTIT\_OUTPUT\_MASK\_PTRS) will have stable values. When output is directed to memory, a store, fence, or architecturally serializing instruction may be required to ensure that the packet data is globally observed. No special packets are generated by disabling packet generation, though a TIP.PGD may result if PacketEn=1 at the time of disable.

### Other Writes to IA32\_RTIT\_CTL

Any attempt to modify IA32\_RTIT\_CTL while TraceEn is set will result in a general-protection fault (#GP) unless the same write also clears TraceEn. However, writes to IA32\_RTIT\_CTL that do not modify any bits will not cause a #GP, even if TraceEn remains set.

#### 33.2.8.4 IA32\_RTIT\_STATUS MSR

The IA32\_RTIT\_STATUS MSR is readable and writable by software, though some fields cannot be modified by software. See Table 33-7 for details. The WRMSR instruction ignores these bits in the source operand (attempts to modify these bits are ignored and do not cause WRMSR to fault).

This MSR can only be written when IA32\_RTIT\_CTL.TraceEn is 0; otherwise WRMSR causes a general-protection fault (#GP). The processor does not modify the value of this MSR while TraceEn is 0 (software can modify it with WRMSR).

**Table 33-7. IA32\_RTIT\_STATUS MSR**

| Position | Bit Name  | At Reset | Bit Description                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------|-----------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0        | FilterEn  | 0        | This bit is written by the processor, and indicates that tracing is allowed for the current IP, see Section 33.2.6.5. Writes are ignored.                                                                                                                                                                                                                                                                                                                 |
| 1        | ContextEn | 0        | The processor sets this bit to indicate that tracing is allowed for the current context. See Section 33.2.6.3. Writes are ignored.                                                                                                                                                                                                                                                                                                                        |
| 2        | TriggerEn | 0        | The processor sets this bit to indicate that tracing is enabled. See Section 33.2.6.2. Writes are ignored.                                                                                                                                                                                                                                                                                                                                                |
| 3        | Reserved  | 0        | Must be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 4        | Error     | 0        | The processor sets this bit to indicate that an operational error has been encountered. When this bit is set, TriggerEn is cleared to 0 and packet generation is disabled. For details, see "ToPA Errors" in Section 33.2.7.2.<br><br>When TraceEn is cleared, software can write this bit. Once it is set, only software can clear it. It is not recommended that software ever set this bit, except in cases where it is restoring a prior saved state. |
| 5        | Stopped   | 0        | The processor sets this bit to indicate that a ToPA Stop condition has been encountered. When this bit is set, TriggerEn is cleared to 0 and packet generation is disabled. For details, see "ToPA STOP" in Section 33.2.7.2.<br><br>When TraceEn is cleared, software can write this bit. Once it is set, only software can clear it. It is not recommended that software ever set this bit, except in cases where it is restoring a prior saved state.  |
| 6        | PendPSB   | 0        | If IA32_RTIT_CTL.InjectPsbPmiOnEnable[56] = 1, the processor sets this bit when the threshold for a PSB+ to be inserted has been reached. The processor will clear this bit when the PSB+ has been inserted into the trace. If PendPSB = 1 and InjectPsbPmiOnEnable = 1 when IA32_RTIT_CTL.TraceEn[0] transitions from 0 to 1, a PSB+ will be inserted into the trace.<br><br>This field is reserved if CPUID.(EAX=14H, ECX=0):EBX[bit 6] = 0.            |

**Table 33-7. IA32\_RTIT\_STATUS MSR**

| Position | Bit Name      | At Reset | Bit Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| 7        | PendTopaPMI   | 0        | If IA32_RTIT_CTL.InjectPsbPmiOnEnable[56] = 1, the processor sets this bit when the threshold for a ToPA PMI to be inserted has been reached. Software should clear this bit once the ToPA PMI has been handled, see “ToPA PMI” for details. If PendTopaPMI = 1 and InjectPsbPmiOnEnable = 1 when IA32_RTIT_CTL.TraceEn[0] transitions from 0 to 1, a PMI will be pended.<br>This field is reserved if CPUID.(EAX=14H, ECX=0):EBX[bit 6] = 0.                                                                              |
| 31:8     | Reserved      | 0        | Must be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 48:32    | PacketByteCnt | 0        | This field is written by the processor, and holds a count of packet bytes that have been sent out. The processor also uses this field to determine when the next PSB packet should be inserted. Note that the processor may clear or modify this field at any time while IA32_RTIT_CTL.TraceEn=1. It will have a stable value when IA32_RTIT_CTL.TraceEn=0. See Section 33.4.2.17 for details.<br>This field is reserved when CPUID.(EAX=14H,ECX=0):EBX[bit 1] (“Configurable PSB and CycleAccurate Mode Supported”) is 0. |
| 63:49    | Reserved      | 0        | Must be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### 33.2.8.5 IA32\_RTIT\_ADDRn\_A and IA32\_RTIT\_ADDRn\_B MSRs

The role of the IA32\_RTIT\_ADDRn\_A/B register pairs, for each n, is determined by the corresponding ADDRn\_CFG fields in IA32\_RTIT\_CTL (see Section 33.2.8.2). The number of these register pairs is enumerated by CPUID.(EAX=14H, ECX=1):EAX.RANGECNT[2:0].

- Processors that enumerate support for 1 range support:
  - IA32\_RTIT\_ADDR0\_A, IA32\_RTIT\_ADDR0\_B
- Processors that enumerate support for 2 ranges support:
  - IA32\_RTIT\_ADDR0\_A, IA32\_RTIT\_ADDR0\_B
  - IA32\_RTIT\_ADDR1\_A, IA32\_RTIT\_ADDR1\_B
- Processors that enumerate support for 3 ranges support:
  - IA32\_RTIT\_ADDR0\_A, IA32\_RTIT\_ADDR0\_B
  - IA32\_RTIT\_ADDR1\_A, IA32\_RTIT\_ADDR1\_B
  - IA32\_RTIT\_ADDR2\_A, IA32\_RTIT\_ADDR2\_B
- Processors that enumerate support for 4 ranges support:
  - IA32\_RTIT\_ADDR0\_A, IA32\_RTIT\_ADDR0\_B
  - IA32\_RTIT\_ADDR1\_A, IA32\_RTIT\_ADDR1\_B
  - IA32\_RTIT\_ADDR2\_A, IA32\_RTIT\_ADDR2\_B
  - IA32\_RTIT\_ADDR3\_A, IA32\_RTIT\_ADDR3\_B

Each register has a single 64-bit field that holds a linear address value. Writes must ensure that the address is in canonical form, otherwise a general-protection fault (#GP) fault will result.

Each MSR can be written only when IA32\_RTIT\_CTL.TraceEn is 0; otherwise WRMSR causes a general-protection fault (#GP).

### 33.2.8.6 IA32\_RTIT\_CR3\_MATCH MSR

The IA32\_RTIT\_CR3\_MATCH register is compared against CR3 when IA32\_RTIT\_CTL.CR3Filter is 1. Bits 63:5 hold the CR3 address value to match, bits 4:0 are reserved to 0. For more details on CR3 filtering and the treatment of this register, see Section 33.2.5.2.

This MSR is accessible if CPUID.(EAX=14H, ECX=0):EBX[bit 0], "CR3 Filtering Support", is 1. This MSR can be written only when IA32\_RTIT\_CTL.TraceEn is 0; otherwise WRMSR causes a general-protection fault (#GP). IA32\_RTIT\_CR3\_MATCH[4:0] are reserved and must be 0; an attempt to set those bits using WRMSR causes a #GP.

### 33.2.8.7 IA32\_RTIT\_OUTPUT\_BASE MSR

This MSR is used to configure the trace output destination, when output is directed to memory (IA32\_RTIT\_CTL.FabricEn = 0). The size of the address field is determined by the maximum physical address width (MAXPHYADDR), as reported by CPUID.80000008H:EAX[7:0].

When the ToPA output scheme is used, the processor may update this MSR when packet generation is enabled, and those updates are asynchronous to instruction execution. Therefore, the values in this MSR should be considered unreliable unless packet generation is disabled (IA32\_RTIT\_CTL.TraceEn = 0).

Accesses to this MSR are supported only if Intel PT output to memory is supported, hence when either CPUID.(EAX=14H, ECX=0):ECX[bit 0] or CPUID.(EAX=14H, ECX=0):ECX[bit 2] are set. Otherwise WRMSR or RDMSR cause a general-protection fault (#GP). If supported, this MSR can be written only when IA32\_RTIT\_CTL.TraceEn is 0; otherwise WRMSR causes a general-protection fault (#GP).

**Table 33-8. IA32\_RTIT\_OUTPUT\_BASE MSR**

| Position       | Bit Name     | At Reset | Bit Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------|--------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6:0            | Reserved     | 0        | Must be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| MAXPHYADDR-1:7 | BasePhysAddr | 0        | The base physical address. How this address is used depends on the value of IA32_RTIT_CTL.ToPA:<br>0: This is the base physical address of a single, contiguous physical output region. This could be mapped to DRAM or to MMIO, depending on the value.<br>The base address should be aligned with the size of the region, such that none of the 1s in the mask value(Section 33.2.8.8) overlap with 1s in the base address. If the base is not aligned, an operational error will result (see Section 33.3.10).<br>1: The base physical address of the current ToPA table. The address must be 4K aligned. Writing an address in which bits 11:7 are non-zero will not cause a #GP, but an operational error will be signaled once TraceEn is set. See "ToPA Errors" in Section 33.2.7.2, as well as Section 33.3.10. |
| 63:MAXPHYADDR  | Reserved     | 0        | Must be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

### 33.2.8.8 IA32\_RTIT\_OUTPUT\_MASK\_PTRS MSR

This MSR holds any mask or pointer values needed to indicate where the next byte of trace output should be written. The meaning of the values held in this MSR depend on whether the ToPA output mechanism is in use. See Section 33.2.7.2 for details.

The processor updates this MSR while when packet generation is enabled, and those updates are asynchronous to instruction execution. Therefore, the values in this MSR should be considered unreliable unless packet generation is disabled (IA32\_RTIT\_CTL.TraceEn = 0).

Accesses to this MSR are supported only if Intel PT output to memory is supported, hence when either CPUID.(EAX=14H, ECX=0):ECX[bit 0] or CPUID.(EAX=14H, ECX=0):ECX[bit 2] are set. Otherwise WRMSR or RDMSR cause a general-protection fault (#GP). If supported, this MSR can be written only when IA32\_RTIT\_CTL.TraceEn is 0; otherwise WRMSR causes a general-protection fault (#GP).

**Table 33-9. IA32\_RTIT\_OUTPUT\_MASK\_PTRS MSR**

| Position | Bit Name          | At Reset | Bit Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------|-------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6:0      | LowerMask         | 7FH      | Forced to 1, writes are ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 31:7     | MaskOrTableOffset | 0        | The use of this field depends on the value of IA32_RTIT_CTL.ToPA:<br>0: This field holds bits 31:7 of the mask value for the single, contiguous physical output region. The size of this field indicates that regions can be of size 128B up to 4GB. This value (combined with the lower 7 bits, which are reserved to 1) will be ANDed with the OutputOffset field to determine the next write address. All 1s in this field should be consecutive and starting at bit 7, otherwise the region will not be contiguous, and an operational error (Section 33.3.10) will be signaled when TraceEn is set.<br>1: This field holds bits 27:3 of the offset pointer into the current ToPA table. This value can be added to the IA32_RTIT_OUTPUT_BASE value to produce a pointer to the current ToPA table entry, which itself is a pointer to the current output region. In this scenario, the lower 7 reserved bits are ignored. This field supports tables up to 256 MBytes in size. |
| 63:32    | OutputOffset      | 0        | The use of this field depends on the value of IA32_RTIT_CTL.ToPA:<br>0: This is bits 31:0 of the offset pointer into the single, contiguous physical output region. This value will be added to the IA32_RTIT_OUTPUT_BASE value to form the physical address at which the next byte of packet output data will be written. This value must be less than or equal to the MaskOrTableOffset field, otherwise an operational error (Section 33.3.10) will be signaled when TraceEn is set.<br>1: This field holds bits 31:0 of the offset pointer into the current ToPA output region. This value will be added to the output region base field, found in the current ToPA table entry, to form the physical address at which the next byte of trace output data will be written.<br>This value must be less than the ToPA entry size, otherwise an operational error (Section 33.3.10) will be signaled when TraceEn is set.                                                          |

### 33.2.9 Interaction of Intel® Processor Trace and Other Processor Features

#### 33.2.9.1 Intel® Transactional Synchronization Extensions (Intel® TSX)

The operation of Intel TSX is described in Chapter 14 of the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1. For tracing purpose, packet generation does not distinguish between hardware lock elision (HLE) and restricted transactional memory (RTM), but speculative execution does have impacts on the trace output. Specifically, packets are generated as instructions complete, even for instructions in a transactional region that is later aborted. For this reason, debugging software will need indication of the beginning and end of a transactional region; this will allow software to understand when instructions are part of a transactional region and whether that region has been committed.

To enable this, TSX information is included in a MODE packet leaf. The mode bits in the leaf are:

- **InTX:** Set to 1 on an TSX transaction begin, and cleared on transaction commit or abort.
- **TXAbort:** Set to 1 only when InTX transitions from 1 to 0 on an abort. Cleared otherwise.

If BranchEn=1, this MODE packet will be sent each time the transaction status changes. See Table 33-10 for details.

**Table 33-10. TSX Packet Scenarios with BranchEn=1**

| TSX Event          | Instruction                                                                                              | Packets                                 |
|--------------------|----------------------------------------------------------------------------------------------------------|-----------------------------------------|
| Transaction Begin  | Either XBEGIN or XACQUIRE lock (the latter if executed transactionally)                                  | MODE(TXAbort=0, InTX=1), FUP(CurrentIP) |
| Transaction Commit | Either XEND or XRELEASE lock, if transactional execution ends. This happens only on the outermost commit | MODE(TXAbort=0, InTX=0), FUP(CurrentIP) |

**Table 33-10. TSX Packet Scenarios with BranchEn=1**

| TSX Event         | Instruction                                                                                                                                                                                                                               | Packets                                                 |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------|
| Transaction Abort | XABORT or other transactional abort                                                                                                                                                                                                       | MODE(TXAAbort=1, InTX=0), FUP(CurrentIP), TIP(TargetIP) |
| Other             | One of the following: <ul style="list-style-type: none"> <li>▪ Nested XBEGIN or XACQUIRE lock</li> <li>▪ An outer XACQUIRE lock that doesn't begin a transaction (InTX not set)</li> <li>▪ Non-outermost XEND or XRELEASE lock</li> </ul> | None. No change to TSX mode bits for these cases.       |

The CurrentIP listed above is the IP of the associated instruction. The TargetIP is the IP of the next instruction to be executed; for HLE, this is the XACQUIRE lock; for RTM, this is the fallback handler.

Intel PT stores are non-transactional, and thus packet writes are not rolled back on TSX abort.

### 33.2.9.2 TSX and IP Filtering

A complication with tracking transactions is handling transactions that start or end outside of the tracing region. Transactions can't span across a change in ContextEn, because CPL changes and CR3 changes each cause aborts. But a transaction can start within the IP filter region and end outside it.

To assist the decoder handling this situation, MODE.TSX packets can be sent even if FilterEn=0, though there will be no FUP attached. Instead, they will merely serve to indicate to the decoder when transactions are active and when they are not. When tracing resumes (due to PacketEn=1), the last MODE.TSX preceding the TIP.PGE will indicate the current transaction status.

### 33.2.9.3 System Management Mode (SMM)

SMM code has special privileges that non-SMM code does not have. Intel Processor Trace can be used to trace SMM code, but special care is taken to ensure that SMM handler context is not exposed in any non-SMM trace collection. Additionally, packet output from tracing non-SMM code cannot be written into memory space that is either protected by SMRR or used by the SMM handler.

SMM is entered via a system management interrupt (SMI). SMI delivery saves the value of IA32\_RTIT\_CTL.TraceEn into SMRAM and then clears it, thereby disabling packet generation.

The saving and clearing of IA32\_RTIT\_CTL.TraceEn ensures two things:

1. All internally buffered packet data is flushed before entering SMM (see Section 33.2.8.2).
2. Packet generation ceases before entering SMM, so any tracing that was configured outside SMM does not continue into SMM. No SMM instruction pointers or other state will be exposed in the non-SMM trace.

When the RSM instruction is executed to return from SMM, the TraceEn value that was saved by SMI delivery is restored, allowing tracing to be resumed. As is done any time packet generation is enabled, ContextEn is re-evaluated, based on the values of CPL, CR3, etc., established by RSM.

Like other interrupts, delivery of an SMI produces a FUP containing the IP of the next instruction to execute. By toggling TraceEn, SMI and RSM can produce TIP.PGD and TIP.PGE packets, respectively, indicating that tracing was disabled or re-enabled. See Table 33.7 for more information about packets entering and leaving SMM.

Although #SMI and RSM change CR3, PIP packets are not generated in these cases. With #SMI tracing is disabled before the CR3 change; with RSM TraceEn is restored after CR3 is written.

TraceEn must be cleared before executing RSM, otherwise it will cause a shutdown. Further, on processors that restrict use of Intel PT with LBRs (see Section 33.3.1.2), any RSM that results in enabling of both will cause a shutdown.

Intel PT can support tracing of System Transfer Monitor operating in SMM, see Section 33.6.

### 33.2.9.4 Virtual-Machine Extensions (VMX)

Initial implementations of Intel Processor Trace do not support tracing in VMX operation. Such processors indicate this by returning 0 for IA32\_VMX\_MISC[bit 14]. On these processors, execution of the VMXON instruction clears IA32\_RTIT\_CTL.TraceEn and any attempt to write IA32\_RTIT\_CTL in VMX operation causes a general-protection exception (#GP).

Processors that support Intel Processor Trace in VMX operation return 1 for IA32\_VMX\_MISC[bit 14]. Details of tracing in VMX operation are described in Section 33.4.2.26.

### 33.2.9.5 Intel® Software Guard Extensions (Intel® SGX)

Intel SGX provides an application with the ability to instantiate a protective container (an enclave) with confidentiality and integrity (see the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3D). On a processor with both Intel PT and Intel SGX enabled, when executing code within a production enclave, no control flow packets are produced by Intel PT. An enclave entry will clear ContextEn, thereby blocking control flow packet generation. A TIP.PGD packet will be generated if PacketEn=1 at the time of the entry.

Upon enclave exit, ContextEn will no longer be forced to 0. If other enables are set at the time, a TIP.PGE may be generated to indicate that tracing is resumed.

During the enclave execution, Intel PT remains enabled, and periodic or timing packets such as PSB, TSC, MTC, or CBR can still be generated. No IPs or other architectural state will be exposed.

For packet generation examples on enclave entry or exit, see Section 33.7.

#### Debug Enclaves

Intel SGX allows an enclave to be configured with relaxed protection of confidentiality for debug purposes, see the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3D. In a debug enclave, Intel PT continues to function normally. Specifically, ContextEn is not impacted by an enclave entry or exit. Hence, the generation of ContextEn-dependent packets within a debug enclave is allowed.

### 33.2.9.6 SENTER/ENTERACCS and ACM

GETSEC[SENTER] and GETSEC[ENTERACCS] instructions clear TraceEn, and it is not restored when those instruction complete. SENTER also causes TraceEn to be cleared on other logical processors when they rendezvous and enter the SENTER sleep state. In these two cases, the disabling of packet generation is not guaranteed to flush internally buffered packets. Some packets may be dropped.

When executing an authenticated code module (ACM), packet generation is silently disabled during ACRAM setup. TraceEn will be cleared, but no TIP.PGD packet is generated. After completion of the module, the TraceEn value will be restored. There will be no TIP.PGE packet, but timing packets, like TSC and CBR, may be produced.

### 33.2.9.7 Intel® Memory Protection Extensions (Intel® MPX)

Bounds exceptions (#BR) caused by Intel MPX are treated like other exceptions, producing FUP and TIP packets that indicate the source and destination IPs.

## 33.3 CONFIGURATION AND PROGRAMMING GUIDELINE

### 33.3.1 Detection of Intel Processor Trace and Capability Enumeration

Processor support for Intel Processor Trace is indicated by CPUID.(EAX=07H,ECX=0H):EBX[bit 25] = 1. CPUID function 14H is dedicated to enumerate the resource and capability of processors that report CPUID.(EAX=07H,ECX=0H):EBX[bit 25] = 1. Different processor generations may have architecturally-defined variation in capabilities. Table 33-11 describes details of the enumerable capabilities that software must use across generations of processors that support Intel Processor Trace.

**Table 33-11. CPUID Leaf 14H Enumeration of Intel Processor Trace Capabilities**

| CPUID.(EAX=14H,ECX=0) |      | Name                                                                               | Description Behavior                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Register              | Bits |                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| EAX                   | 31:0 | Maximum valid sub-leaf Index                                                       | Specifies the index of the maximum valid sub-leaf for this CPUID leaf.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| EBX                   | 0    | CR3 Filtering Support                                                              | 1: Indicates that IA32_RTIT_CTL.CR3Filter can be set to 1, and that IA32_RTIT_CR3_MATCH MSR can be accessed. See Section 33.2.8.<br>0: Indicates that writes that set IA32_RTIT_CTL.CR3Filter to 1, or any access to IA32_RTIT_CR3_MATCH, will generate a #GP exception.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                       | 1    | Configurable PSB and Cycle-Accurate Mode Supported                                 | 1: (a) IA32_RTIT_CTL.PSBFreq can be set to a non-zero value, in order to select the preferred PSB frequency (see below for allowed values). (b) IA32_RTIT_STATUS.PacketByteCnt can be set to a non-zero value, and will be incremented by the processor when tracing to indicate progress towards the next PSB. If trace packet generation is enabled by setting TraceEn, a PSB will only be generated if PacketByteCnt=0. (c) IA32_RTIT_CTL.CYCEn can be set to 1 to enable Cycle-Accurate Mode. See Section 33.2.8.<br>0: (a) Any attempt to write a non-zero value to IA32_RTIT_CTL.PSBFreq or IA32_RTIT_STATUS.PacketByteCnt will generate a #GP exception. (b) If trace packet generation is enabled by setting TraceEn, a PSB is always generated. (c) Any attempt to write a non-zero value to IA32_RTIT_CTL.CYCEn or IA32_RTIT_CTL.CycThresh will generate a #GP exception.        |
|                       | 2    | IP Filtering and TraceStop supported, and Preserve Intel PT MSRs across warm reset | 1: (a) IA32_RTIT_CTL provides at one or more ADDRn_CFG field to configure the corresponding address range MSRs for IP Filtering or IP TraceStop. Each ADDRn_CFG field accepts a value in the range of 0:2 inclusive. The number of ADDRn_CFG fields is reported by CPUID.(EAX=14H, ECX=1):EAX.RANGE_CNT[2:0]. (b) At least one register pair IA32_RTIT_ADDRn_A and IA32_RTIT_ADDRn_B are provided to configure address ranges for IP filtering or IP TraceStop. (c) On warm reset, all Intel PT MSRs will retain their pre-reset values, though IA32_RTIT_CTL.TraceEn will be cleared. The Intel PT MSRs are listed in Section 33.2.8.<br>0: (a) An Attempt to write IA32_RTIT_CTL.ADDRn_CFG with non-zero encoding values will cause #GP. (b) Any access to IA32_RTIT_ADDRn_A and IA32_RTIT_ADDRn_B, will generate a #GP exception. (c) On warm reset, all Intel PT MSRs will be cleared. |
|                       | 3    | MTC Supported                                                                      | 1: IA32_RTIT_CTL.MTCEn can be set to 1, and MTC packets will be generated. See Section 33.2.8.<br>0: An attempt to set IA32_RTIT_CTL.MTCEn or IA32_RTIT_CTL.MTCFreq to a non-zero value will generate a #GP exception.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                       | 4    | PTWRITE Supported                                                                  | 1: Writes can set IA32_RTIT_CTL[12] (PTWEn) and IA32_RTIT_CTL[5] (FUPonPTW), and PTWRITE can generate packets.<br>0: Writes that set IA32_RTIT_CTL[12] or IA32_RTIT_CTL[5] will generate a #GP exception, and PTWRITE will #UD fault.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                       | 5    | Power Event Trace Supported                                                        | 1: Writes can set IA32_RTIT_CTL[4] (PwrEvtEn), enabling Power Event Trace packet generation.<br>0: Writes that set IA32_RTIT_CTL[4] will generate a #GP exception.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### 33.3.1.1 Packet Decoding of RIP versus LIP

FUP, TIP, TIP.PGE, and TIP.PGE packets can contain an instruction pointer (IP) payload. On some processor generations, this payload will be an effective address (RIP), while on others this will be a linear address (LIP). In the former case, the payload is the offset from the current CS base address, while in the latter it is the sum of the offset and the CS base address (Note that in real mode, the CS base address is the value of CS<<4, while in protected mode the CS base address is the base linear address of the segment indicated by the CS register.). Which IP type is in use is indicated by enumeration (see CPUID.(EAX=14H, ECX=0):ECX.LIP[bit 31] in Table 33-11).

For software that executes while the CS base address is 0 (including all software executing in 64-bit mode), the difference is indistinguishable. A trace decoder must account for cases where the CS base address is not 0 and the resolved LIP will not be evident in a trace generated on a CPU that enumerates use of RIP. This is likely to cause problems when attempting to link the trace with the associated binaries.

Note that IP comparison logic, for IP filtering and TraceStop range calculation, is based on the same IP type as these IP packets. For processors that output RIP, the IP comparison mechanism is also based on RIP, and hence on those processors RIP values should be written to IA32\_RTIT\_ADDRn\_[AB] MSRs. This can produce differing behavior if the same trace configuration setting is run on processors reporting different IP types, i.e., CPUID.(EAX=14H, ECX=0):ECX.LIP[bit 31]. Care should be taken to check CPUID when configuring IP filters.

### 33.3.1.2 Model Specific Capability Restrictions

Some processor generations impose restrictions that prevent use of LBRs/BTS/BTM/LERs when software has enabled tracing with Intel Processor Trace. On these processors, when TraceEn is set, updates of LBR, BTS, BTM, LERs are suspended but the states of the corresponding IA32\_DEBUGCTL control fields remained unchanged as if it were still enabled. When TraceEn is cleared, the LBR array is reset, and LBR/BTS/BTM/LERs updates will resume. Further, reads of these registers will return 0, and writes will be dropped.

The list of MSRs whose updates/accesses are restricted follows.

- MSR\_LASTBRANCH\_x\_TO\_IP, MSR\_LASTBRANCH\_x\_FROM\_IP, MSR\_LBR\_INFO\_x, MSR\_LASTBRANCH\_TOS
- MSR\_LER\_FROM\_LIP, MSR\_LER\_TO\_LIP
- MSR\_LBR\_SELECT

For processors with CPUID DisplayFamily\_DisplayModel signatures of 06\_3DH, 06\_47H, 06\_4EH, 06\_4FH, 06\_56H, and 06\_5EH, the use of Intel PT and LBRs are mutually exclusive.

## 33.3.2 Enabling and Configuration of Trace Packet Generation

To configure trace packets, enable packet generation, and capture packets, software starts with using CPUID instruction to detect its feature flag, CPUID.(EAX=07H,ECX=0H):EBX[bit 25] = 1; followed by enumerating the capabilities described in Section 33.3.1.

Based on the capability queried from Section 33.3.1, software must configure a number of model-specific registers. This section describes programming considerations related to those MSRs.

### 33.3.2.1 Enabling Packet Generation

When configuring and enabling packet generation, the IA32\_RTIT\_CTL MSR should be written after any other Intel PT MSRs have been written, since writes to the other configuration MSRs cause a general-protection fault (#GP) if TraceEn = 1. If a prior trace collection context is not being restored, then software should first clear IA32\_RTIT\_STATUS. This is important since the Stopped, and Error fields are writable; clearing the MSR clears any values that may have persisted from prior trace packet collection contexts. See Section 33.2.8.2 for details of packets generated by setting TraceEn to 1.

If setting TraceEn to 1 causes an operational error (see Section 33.3.10), there may be a delay after the WRMSR completes before the error is signaled in the IA32\_RTIT\_STATUS MSR.

While packet generation is enabled, the values of some configuration MSRs (e.g., IA32\_RTIT\_STATUS and IA32\_RTIT\_OUTPUT\_\*) are transient, and reads may return values that are out of date. Only after packet generation is disabled (by clearing TraceEn) do reads of these MSRs return reliable values.

### 33.3.2.2 Disabling Packet Generation

After disabling packet generation by clearing IA32\_RTIT\_CTL, it is advisable to read the IA32\_RTIT\_STATUS MSR (Section 33.2.8.4):

- If the Error bit is set, an operational error was encountered, and the trace is most likely compromised. Software should check the source of the error (by examining the output MSR values), correct the source of the problem, and then attempt to gather the trace again. For details on operational errors, see Section 33.3.10. Software should clear IA32\_RTIT\_STATUS.Error before re-enabling packet generation.
- If the Stopped bit is set, software execution encountered an IP TraceStop (see Section 33.2.5.3) or the ToPA Stop condition (see “ToPA STOP” in Section 33.2.7.2) before packet generation was disabled.

### 33.3.3 Flushing Trace Output

Packets are first buffered internally and then written out asynchronously. To collect packet output for post-processing, a collector needs first to ensure that all packet data has been flushed from internal buffers. Software can ensure this by stopping packet generation by clearing IA32\_RTIT\_CTL.TraceEn (see “Disabling Packet Generation” in Section 33.2.8.2).

When software clears IA32\_RTIT\_CTL.TraceEn to flush out internally buffered packets, the logical processor issues an SFENCE operation which ensures that WC trace output stores will be ordered with respect to the next store, or serializing operation. A subsequent read from the same logical processor will see the flushed trace data, while a read from another logical processor should be preceded by a store, fence, or architecturally serializing operation on the tracing logical processor.

When the flush operations complete, the IA32\_RTIT\_OUTPUT\_\* MSR values indicate where the trace ended. While TraceEn is set, these MSRs may hold stale values. Further, if a ToPA region with INT=1 is filled, meaning a ToPA PMI has been triggered, IA32\_PERF\_GLOBAL\_STATUS.Trace\_ToPA\_PMI[55] will be set by the time the flush completes.

### 33.3.4 Warm Reset

The MSRs software uses to program Intel Processor Trace are cleared after a power-on RESET (or cold RESET). On a warm RESET, the contents of those MSRs can retain their values from before the warm RESET with the exception that IA32\_RTIT\_CTL.TraceEn will be cleared (which may have the side effect of clearing some bits in IA32\_RTIT\_STATUS).

### 33.3.5 Context Switch Consideration

To facilitate construction of instruction execution traces at the granularity of a software process or thread context, software can save and restore the states of the trace configuration MSRs across the process or thread context switch boundary. The principle is the same as saving and restoring the typical architectural processor states across context switches.

#### 33.3.5.1 Manual Trace Configuration Context Switch

The configuration can be saved and restored through a sequence of instructions of RDMSR, management of MSR content and WRMSR. To stop tracing and to ensure that all configuration MSRs contain stable values, software must clear IA32\_RTIT\_CTL.TraceEn before reading any other trace configuration MSRs. The recommended method for saving trace configuration context manually follows:

1. RDMSR IA32\_RTIT\_CTL, save value to memory
2. WRMSR IA32\_RTIT\_CTL with saved value from RDMSR above and TraceEn cleared
3. RDMSR all other configuration MSRs whose values had changed from previous saved value, save changed values to memory

When restoring the trace configuration context, IA32\_RTIT\_CTL should be restored last:

1. Read saved configuration MSR values, aside from IA32\_RTIT\_CTL, from memory, and restore them with WRMSR
2. Read saved IA32\_RTIT\_CTL value from memory, and restore with WRMSR.

### 33.3.5.2 Trace Configuration Context Switch Using XSAVES/XRSTORS

On processors whose XSAVE feature set supports XSAVES and XRSTORS, the Trace configuration state can be saved using XSAVES and restored by XRSTORS, in conjunction with the bit field associated with supervisory state component in IA32\_XSS. See Chapter 13, “Managing State Using the XSAVE Feature Set” of Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1.

### 33.3.6 Cycle-Accurate Mode

Intel PT can be run in a cycle-accurate mode which enables CYC packets (see Section 33.4.2.14) that provide low-level information in the processor core clock domain. This cycle counter data in CYC packets can be used to compute IPC (Instructions Per Cycle), or to track wall-clock time on a fine-grain level.

To enable cycle-accurate mode packet generation, software should set IA32\_RTIT\_CTL.CYCEn=1. It is recommended that software also set TSCEn=1 anytime cycle-accurate mode is in use. With this, all CYC-eligible packets will be preceded by a CYC packet, the payload of which indicates the number of core clock cycles since the last CYC packet. In cases where multiple CYC-eligible packets are generated in a single cycle, only a single CYC will be generated before the CYC-eligible packets, otherwise each CYC-eligible packet will be preceded by its own CYC. The CYC-eligible packets are:

- TNT, TIP, TIP.PGE, TIP.PGD, MODE.EXEC, MODE.TSX, PIP, VMCS, OVF, MTC, TSC, PTWRITE, EXSTOP

TSC packets are generated when there is insufficient information to reconstruct wall-clock time, due to tracing being disabled (TriggerEn=0), or power down scenarios like a transition to a deep-sleep MWAIT C-state. In this case, the CYC that is generated along with the TSC will indicate the number of cycles actively tracing (those powered up, with TriggerEn=1) executed between the last CYC packet and the TSC packet. And hence the amount of time spent while tracing is inactive can be inferred from the difference in time between that expected based on the CYC value, and the actual time indicated by the TSC.

Additional CYC packets may be sent stand-alone, so that the processor can ensure that the decoder is aware of the number of cycles that have passed before the internal hardware counter wraps, or is reset due to other micro-architectural condition. There is no guarantee at what intervals these standalone CYC packets will be sent, except that they will be sent before the wrap occurs. An illustration is given below.

**Example 33-1. An Illustrative CYC Packet Example**

| Time (cycles) | Instruction Snapshot | Generated Packets | Comment                                                   |
|---------------|----------------------|-------------------|-----------------------------------------------------------|
| x             | call %eax            | CYC(?), TIP       | ?Elapsed cycles from the previous CYC unknown             |
| x + 2         | call %ebx            | CYC(2), TIP       | 1 byte CYC packet; 2 cycles elapsed from the previous CYC |
| x + 8         | jnz Foo (not taken)  | CYC(6)            | 1 byte CYC packet                                         |
| x + 9         | ret (compressed)     |                   |                                                           |
| x + 12        | jnz Bar (taken)      |                   |                                                           |
| x + 16        | ret (uncompressed)   | TNT, CYC(8), TIP  | 1 byte CYC packet                                         |
| x + 4111      |                      | CYC(4095)         | 2 byte CYC packet                                         |
| x + 12305     |                      | CYC(8194)         | 3 byte CYC packet                                         |
| x + 16332     | mov cr3, %ebx        | CYC(4027), PIP    | 2 byte CYC packet                                         |

### 33.3.6.1 Cycle Counter

The cycle counter is implemented in hardware (independent of the time stamp counter or performance monitoring counters), and is a simple incrementing counter that does not saturate, but rather wraps. The size of the counter is implementation specific.

The cycle counter is reset to zero any time that TriggerEn is cleared, and when a CYC packet is sent. The cycle counter will continue to count when ContextEn or FilterEn are cleared, and cycle packets will still be generated. It will not count during sleep states that result in Intel PT logic being powered-down, but will count up to the point where clocks are disabled, and resume counting once they are re-enabled.

### 33.3.6.2 Cycle Packet Semantics

Cycle-accurate mode adheres to the following protocol:

- All packets that precede a CYC packet represent instructions or events that took place before the CYC time.
- All packets that follow a CYC packet represent instructions or events that took place at the same time as, or after, the CYC time.
- The CYC-eligible packet that immediately follows a CYC packet represents an instruction or event that took place at the same time as the CYC time.

These items above give the decoder a means to apply CYC packets to a specific instruction in the assembly stream. Most packets represent a single instruction or event, and hence the CYC packet that precedes each of those packets represents the retirement time of that instruction or event. In the case of TNT packets, up to 6 conditional branches and/or compressed RETs may be contained in the packet. In this case, the preceding CYC packet provides the retirement time of the first branch in the packet. It is possible that multiple branches retired in the same cycle as that first branch in the TNT, but the protocol will not make that obvious. Also note that a MTC packet could be generated in the same cycle as the first JCC in the TNT packet. In this case, the CYC would precede both the MTC and the TNT, and apply to both.

Note that there are times when the cycle counter will stop counting, though cycle-accurate mode is enabled. After any such scenario, a CYC packet followed by TSC packet will be sent. See Section 33.8.3.2 to understand how to interpret the payload values

#### Multi-packet Instructions or Events

Some operations, such as interrupts or task switches, generate multiple packets. In these cases, multiple CYC packets may be sent for the operation, preceding each CYC-eligible packet in the operation. An example, using a task switch on a software interrupt, is shown below.

**Example 33-2. An Example of CYC in the Presence of Multi-Packet Operations**

| Time (cycles) | Instruction Snapshot | Generated Packets                               |
|---------------|----------------------|-------------------------------------------------|
| x             | jnz Foo (not taken)  | CYC(?)                                          |
| x + 2         | ret (compressed)     |                                                 |
| x + 8         | jnz Bar (taken)      |                                                 |
| x + 9         | jmp %eax             | TNT, CYC(9), TIP                                |
| x + 12        | jnz Bar (not taken)  | CYC(3)                                          |
| x + 32        | int3 (task gate)     | TNT, FUP, CYC(10), PIP, CYC(20), MODE.Exec, TIP |

### 33.3.6.3 Cycle Thresholds

Software can opt to reduce the frequency of cycle packets, a trade-off to save bandwidth and intrusion at the expense of precision. This is done by utilizing a cycle threshold (see Section 33.2.8.2).

IA32\_RTIT\_CTL.CycThresh indicates to the processor the minimum number of cycles that must pass before the next CYC packet should be sent. If this value is 0, no threshold is used, and CYC packets can be sent every cycle in which a CYC-eligible packet is generated. If this value is greater than 0, the hardware will wait until the associated

number of cycles have passed since the last CYC packet before sending another. CPUID provides the threshold options for CycThresh, see Section 33.3.1.

Note that the cycle threshold does not dictate how frequently a CYC packet will be posted, it merely assigns the maximum frequency. If the cycle threshold is 16, a CYC packet can be posted no more frequently than every 16 cycles. However, once that threshold of 16 cycles has passed, it still requires a new CYC-eligible packet to be generated before a CYC will be inserted. Table 33-13 illustrates the threshold behavior.

**Table 33-13. An Illustrative CYC Packet Example**

| Time (cycles) | Instruction Snapshot | Threshold |          |          |          |
|---------------|----------------------|-----------|----------|----------|----------|
|               |                      | 0         | 16       | 32       | 64       |
| x             | jmp %eax             | CYC, TIP  | CYC, TIP | CYC, TIP | CYC, TIP |
| x + 9         | call %ebx            | CYC, TIP  | TIP      | TIP      | TIP      |
| x + 15        | call %ecx            | CYC, TIP  | TIP      | TIP      | TIP      |
| x + 30        | jmp %edx             | CYC, TIP  | CYC, TIP | TIP      | TIP      |
| x + 38        | mov cr3, %eax        | CYC, PIP  | PIP      | CYC, PIP | PIP      |
| x + 46        | jmp [%eax]           | CYC, TIP  | CYC, TIP | TIP      | TIP      |
| x + 64        | call %edx            | CYC, TIP  | CYC, TIP | TIP      | CYC, TIP |
| x + 71        | jmp %edx             | CYC, TIP  | TIP      | CYC, TIP | TIP      |

### 33.3.7 Decoder Synchronization (PSB+)

The PSB packet (Section 33.4.2.17) serves as a synchronization point for a trace-packet decoder. It is a pattern in the trace log for which the decoder can quickly scan to align packet boundaries. No legal packet combination can result in such a byte sequence. As such, it serves as the starting point for packet decode. To decode a trace log properly, the decoder needs more than simply to be aligned: it needs to know some state and potentially some timing information as well. The decoder should never need to retain any information (e.g., LastIP, call stack, compound packet event) across a PSB; all compound packet events will be completed before a PSB, and any compression state will be reset.

When a PSB packet is generated, it is followed by a PSBEND packet (Section 33.4.2.18). One or more packets may be generated in between those two packets, and these inform the decoder of the current state of the processor. These packets, known collectively as PSB+, should be interpreted as “status only”, since they do not imply any change of state at the time of the PSB, nor are they associated directly with any instruction or event. Thus, the normal binding and ordering rules that apply to these packets outside of PSB+ can be ignored when these packets are between a PSB and PSBEND. They inform the decoder of the state of the processor at the time of the PSB.

PSB+ can include:

- Timestamp (TSC), if IA32\_RTIT\_CTL.TSCEn=1.
- Timestamp-MTC Align (TMA), if IA32\_RTIT\_CTL.TSCEn=1 && IA32\_RTIT\_CTL.MTCEn=1.
- Paging Information Packet (PIP), if ContextEn=1 and IA32\_RTIT\_CTL.OS=1. The non-root bit (NR) is set if the logical processor is in VMX non-root operation and the “conceal VMX from PT” VM-execution control is 0.
- VMCS packet, if either the logical is in VMX root operation or the logical processor is in VMX non-root operation and the “conceal VMX from PT” VM-execution control is 0.
- Core Bus Ratio (CBR).
- MODE.TSX, if ContextEn=1 and BranchEn = 1.
- MODE.Exec, if PacketEn=1.
- Flow Update Packet (FUP), if PacketEn=1.

PSB is generated only when TriggerEn=1; hence PSB+ has the same dependencies. The ordering of packets within PSB+ is not fixed. Timing packets such as CYC and MTC may be generated between PSB and PSBEND, and their meanings are the same as outside PSB+.

A PSB+ can be lost in some scenarios. If IA32\_RTIT\_STATUS.TriggerEn is cleared just as the PSB threshold is reached, e.g., due to TraceEn being cleared, the PSB+ may not be generated. On processors that support PSB preservation (CPUID.(EAX=14H, ECX=0):EBX[bit 6] = 1), setting IA32\_RTIT\_CTL.InjectPsbPmiOnEnable[56] = 1 will ensure that a PSB+ that is pending at the time PT is disabled will be recorded by setting IA32\_RTIT\_STATUS.PendPSB[6] = 1. A PSB will be inserted, and PendPSB cleared, when PT is later re-enabled while PendPSB = 1.

Note that an overflow can occur during PSB+, and this could cause the PSBEND packet to be lost. For this reason, the OVF packet should also be viewed as terminating PSB+. If IA32\_RTIT\_STATUS.TriggerEn is cleared just as the PSB threshold is reached, the PSB+ may not be generated. TriggerEn can be cleared by a WRMSR that clears IA32\_RTIT\_CTL.TraceEn, a VM exit that clears IA32\_RTIT\_CTL.TraceEn, an #SMI, or any time that either IA32\_RTIT\_STATUS.Stopped is set (e.g., by a TraceStop or ToPA stop condition) or IA32\_RTIT\_STATUS.Error is set (e.g., by an Intel PT output error). On processors that support PSB preservation (CPUID.(EAX=14H, ECX=0):EBX[bit 6] = 1), setting IA32\_RTIT\_CTL.InjectPsbPmiOnEnable[56] = 1 will ensure that a PSB+ that is pending at the time PT is disabled will be recorded by setting IA32\_RTIT\_STATUS.PendPSB[6] = 1. A PSB will then be pended when the saved PT context is later restored.

### 33.3.8 Internal Buffer Overflow

In the rare circumstances when new packets need to be generated but the processor's dedicated internal buffers are all full, an "internal buffer overflow" occurs. On such an overflow packet generation ceases (as packets would need to enter the processor's internal buffer) until the overflow resolves. Once resolved, packet generation resumes.

When the buffer overflow is cleared, an OVF packet (Section 33.4.2.16) is generated, and the processor ensures that packets which follow the OVF are not compressed (IP compression or RET compression) against packets that were lost.

If IA32\_RTIT\_CTL.BranchEn = 1, the OVF packet will be followed by a FUP if the overflow resolves while PacketEn=1. If the overflow resolves while PacketEn = 0 no packet is generated, but a TIP.PGE will naturally be generated later, once PacketEn = 1. The payload of the FUP or TIP.PGE will be the Current IP of the first instruction upon which tracing resumes after the overflow is cleared. If the overflow resolves while PacketEn=1, only timing packets may come between the OVF and the FUP. If the overflow resolves while PacketEn=0, any other packets that are not dependent on PacketEn may come between the OVF and the TIP.PGE.

#### 33.3.8.1 Overflow Impact on Enables

The address comparisons to ADDRn ranges, for IP filtering and TraceStop (Section 33.2.5.3), continue during a buffer overflow, and TriggerEn, ContextEn, and FilterEn may change during a buffer overflow. Like other packets, however, any TIP.PGE or TIP.PGD packets that would have been generated will be lost. Further, IA32\_RTIT\_STATUS.PacketByteCnt will not increment, since it is only incremented when packets are generated.

If a TraceStop event occurs during the buffer overflow, IA32\_RTIT\_STATUS.Stopped will still be set, tracing will cease as a result. However, the TraceStop packet, and any TIP.PGD that result from the TraceStop, may be dropped.

#### 33.3.8.2 Overflow Impact on Timing Packets

Any timing packets that are generated during a buffer overflow will be dropped. If only a few MTC packets are dropped, a decoder should be able to detect this by noticing that the time value in the first MTC packet after the buffer overflow incremented by more than one. If the buffer overflow lasted long enough that 256 MTC packets are lost (and thus the MTC packet 'wraps' its 8-bit CTC value), then the decoder may be unable to properly understand the trace. This is not an expected scenario. No CYC packets are generated during overflow, even if the cycle counter wraps.

Note that, if cycle-accurate mode is enabled, the OVF packet will generate a CYC packet. Because the cycle counter counts during overflows, this CYC packet can provide the duration of the overflow. However, there is a risk that the cycle counter wrapped during the overflow, which could render this CYC misleading.

### 33.3.9 TNT Disable

Software can opt to omit TNT packets from control flow trace (BranchEn=1) by setting IA32\_RTIT\_CTL.DisTNT[bit 55]. This can dramatically reduce trace size. Results will vary by workload, but trace size reductions of 40-75% are typical, which will have a corresponding reduction in performance overhead and memory bandwidth consumption from Intel PT. However, omitting TNT packets means the decoder is not able to follow the full control flow trace, since conditional branch and compressed RET results won't be known. Thus, TNT Disable should be employed only for usages that do not depend on full control flow trace.

#### NOTE

To avoid loss of RET results with TNT Disable, software may wish to disable RET compression by setting IA32\_RTIT\_CTL.DisRETC[bit 11].

### 33.3.10 Operational Errors

Errors are detected as a result of packet output configuration problems, which can include output alignment issues, ToPA reserved bit violations, or overlapping packet output with restricted memory. See “ToPA Errors” in Section 33.2.7.2 for details on ToPA errors, and Section 33.2.7.4 for details on restricted memory errors. Operational errors are only detected and signaled when TraceEn=1.

When an operational error is detected, tracing is disabled and the error is logged. Specifically, IA32\_RTIT\_STATUS.Error is set, which will cause IA32\_RTIT\_STATUS.TriggerEn to be 0. This will disable generation of all packets. Some causes of operational errors may lead to packet bytes being dropped.

It should be noted that the timing of error detection may not be predictable. Errors are signaled when the processor encounters the problematic configuration. This could be as soon as packet generation is enabled but could also be later when the problematic entry or field needs to be used.

Once an error is signaled, software should disable packet generation by clearing TraceEn, diagnose and fix the error condition, and clear IA32\_RTIT\_STATUS.Error. At this point, packet generation can be re-enabled.

## 33.4 TRACE PACKETS AND DATA TYPES

This section details the data packets generated by Intel Processor Trace. It is useful for developers writing the interpretation code that will decode the data packets and apply it to the traced source code.

### 33.4.1 Packet Relationships and Ordering

This section introduces the concept of packet “binding”, which involves determining the IP in a binary disassembly at which the change indicated by a given packet applies. Some packets have the associated IP as the payload (FUP, TIP), while for others the decoder need only search for the next instance of a particular instruction (or instructions) to bind the packet (TNT). However, in many cases, the decoder will need to consider the relationship between packets, and to use this packet context to determine how to bind the packet.

Section 33.4.1.1 below provides detailed descriptions of the packets, including how packets bind to IPs in the disassembly, to other packets, or to nothing at all. Many packets listed are simple to bind, because they are generated in only a few scenarios. Those that require more consideration are typically part of “compound packet events”, such as interrupts, exceptions, and some instructions, where multiple packets are generated by a single operation (instruction or event). These compound packet events frequently begin with a FUP to indicate the source address (if it is not clear from the disassembly), and are concluded by a TIP or TIP.PGD packet that indicates the destination address (if one is provided). In this scenario, the FUP is said to be “coupled” with the TIP packet.

Other packets could be in between the coupled FUP and TIP packet. Timing packets, such as TSC, MTC, CYC, or CBR, could arrive at any time, and hence could intercede in a compound packet event. If an operation changes CR3 or the processor’s mode of execution, a state update packet (i.e., PIP or MODE) is generated. The state changes indicated by these intermediate packets should be applied at the IP of the TIP\* packet. A summary of compound packet events is provided in Table 33-14; see Section 33.4.1.1 for more per-packet details and Section 33.7 for more detailed packet generation examples.

**Table 33-14. Compound Packet Event Summary**

| <b>Event Type</b>                                 | <b>Beginning</b>            | <b>Middle</b>                                    | <b>End</b>            | <b>Comment</b>                                                                                                                                                     |
|---------------------------------------------------|-----------------------------|--------------------------------------------------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Unconditional, uncompressed control-flow transfer | FUP or none                 | Any combination of PIP, VMCS, MODE.Exec, or none | TIP or TIP.PGD        | FUP only for asynchronous events. Order of middle packets may vary.<br>PIP/VMCS/MODE only if the operation modifies the state tracked by these respective packets. |
| TSX Update                                        | MODE.TSX, and (FUP or none) | None                                             | TIP, TIP.PGD, or none | FUP<br>TIP/TIP.PGD only for TSX abort cases.                                                                                                                       |
| Overflow                                          | OVF                         | PSB, PSBEND, or none                             | FUP or TIP.PGE        | FUP if overflow resolves while ContextEn=1, else TIP.PGE.                                                                                                          |

### 33.4.1.1 Packet Blocks

Packet blocks are a means to dump one or more groups of state values. Packet blocks begin with a Block Begin Packet (BBP), which indicates what type of state is held within the block. Following each BBP there may be one or more Block Item Packets (BIPs), which contain the state values. The block is terminated by either a Block End Packet (BEP) or another BBP indicating the start of a new block.

The BIP packet includes an ID value that, when combined with the Type field from the BBP that preceded it, uniquely identifies the state value held in the BIP payload. The size of each BIP packet payload is provided by the Size field in the preceding BBP packet.

Each block type can have up to 32 items defined for it. There is no guarantee, however, that each block of that type will hold all 32 items. For more details on which items to expect, see documentation on the specific block type of interest.

See the BBP packet description (Section 33.4.2.26) for details on packet block generation scenarios.

Packet blocks are entirely generated within an instruction or between instructions, which dictates the types of packets (aside from BIPs) that may be seen within a packet block. Packets that indicate control flow changes, or other indication of instruction completion, cannot be generated within a block. These are listed in the following table. Other packets, including timing packets, may occur between BBP and BEP.

**Table 33-15. Packets Forbidden Between BBP and BEP**

|                       |
|-----------------------|
| TNT                   |
| TIP, TIP.PGE, TIP.PGD |
| MODE.Exec, MODE.TSX   |
| PIP, VMCS             |
| TraceStop             |
| PSB, PSBEND           |
| PTW                   |
| MWAIT                 |

It is possible to encounter an internal buffer overflow in the middle of a block. In such a case, it is guaranteed that packet generation will not resume in the middle of a block, and hence the OVF packet terminates the current block. Depending on the duration of the overflow, subsequent blocks may also be lost.

### Decoder Implications

When a Block Begin Packet (BBP) is encountered, the decoder will need to decode some packets within the block differently from those outside a block. The Block Item Packet (BIP) header byte has the same encoding as a TNT packet outside of a block, but must be treated as a BIP header (with following payload) within one.

When an OVF packet is encountered, the decoder should treat that as a block ending condition. Packet generation will not resume within a block.

### 33.4.2 Packet Definitions

The following description of packet definitions are in tabular format. Figure 33-3 explains how to interpret them. Packet bits listed as "RSVD" are not guaranteed to be 0.

|               | Byte Number                                                                                                                                                             | Bit Number | Header bits in Green |                     |  |  | Payload in White                                                                      |  |  |  |  |  |  |  |  |  |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|----------------------|---------------------|--|--|---------------------------------------------------------------------------------------|--|--|--|--|--|--|--|--|--|
| Name          | Packet name                                                                                                                                                             |            |                      |                     |  |  |                                                                                       |  |  |  |  |  |  |  |  |  |
| Packet Format | Description of fields                                                                                                                                                   |            |                      |                     |  |  |                                                                                       |  |  |  |  |  |  |  |  |  |
| Dependencies  | Depends on packet generation configuration enable controls or other bits (Section 33.2.6).                                                                              |            |                      | Generation Scenario |  |  | Which instructions, events, or other scenarios can cause this packet to be generated. |  |  |  |  |  |  |  |  |  |
| Description   | Description of the packet, including the purpose it serves, meaning of the information or payload, etc                                                                  |            |                      |                     |  |  |                                                                                       |  |  |  |  |  |  |  |  |  |
| Application   | How a decoder should apply this packet. It may bind to a specific instruction from the binary, or to another packet in the stream, or have other implications on decode |            |                      |                     |  |  |                                                                                       |  |  |  |  |  |  |  |  |  |

Figure 33-3. Interpreting Tabular Definition of Packet Format

### 33.4.2.1 Taken/Not-taken (TNT) Packet

**Table 33-16. TNT Packet Definition**

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                 |                 |                     |                 |                                                                                                                                                                                                                                             |                 |                 |           |  |  |   |   |   |   |   |   |   |   |  |   |   |                |                |                |                |                |                |   |           |   |   |   |   |   |   |   |   |   |   |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                |                |                |                 |                 |                 |                 |                 |                 |   |   |                |                |                |                |                |                |                |   |   |   |   |   |   |  |

|               | B1...BN represent the last N conditional branch or compressed RET (Section 33.4.2.2) results, such that B1 is oldest and BN is youngest. The short TNT packet can contain from 1 to 6 TNT bits. The long TNT packet can contain from 1 to 47 TNT bits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                 |                 |                     |                 |                                                                                                                                                                                                                                             |                 |                 |           |  |  |   |   |   |   |   |   |   |   |  |   |   |                |                |                |                |                |                |   |           |   |   |   |   |   |   |   |   |   |   |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                |                |                |                 |                 |                 |                 |                 |                 |   |   |                |                |                |                |                |                |                |   |   |   |   |   |   |  |

|               | Irrespective of how many TNT bits is in a packet, the last valid TNT bit is followed by a trailing 1, or Stop bit, as shown above. If the TNT packet is not full (fewer than 6 TNT bits for the Short TNT, or fewer than 47 TNT bits for the Long TNT), the Stop bit moves up, and the trailing bits of the packet are filled with 0s. Examples of these “partial TNTs” are shown below. An implementation may choose to use long TNTs, short TNTs, or both.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                 |                 |                     |                 |                                                                                                                                                                                                                                             |                 |                 |           |  |  |   |   |   |   |   |   |   |   |  |   |   |                |                |                |                |                |                |   |           |   |   |   |   |   |   |   |   |   |   |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                 |                |                |                |                 |                 |                 |                 |                 |                 |   |   |                |                |                |                |                |                |                |   |   |   |   |   |   |  |

|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | Provides the taken/not-taken results for the last 1.6 (Short TNT) or 1.47 (Long TNT) conditional branches (Jcc, J*CXZ, or LOOP) or compressed RETs (Section 33.4.2.2). The TNT payload bits should be interpreted as follows: <ul style="list-style-type: none"><li>▪ 1 indicates a taken conditional branch, or a compressed RET</li><li>▪ 0 indicates a not-taken conditional branch</li></ul> TNT payload bits are stored internal to the processor in a TNT buffer, until either the buffer is filled or another packet is to be generated. In either case a TNT packet holding the buffered bits will be emitted, and the TNT buffer will be marked as empty. |
| Application | Each valid payload bit (that is, bits between the header bits and the trailing Stop bit) applies to an upcoming conditional branch or RET instruction. Once a decoder consumes a TNT packet with N valid payload bits, these bits should be applied to (and hence provide the destination for) the next N conditional branches or RETs.                                                                                                                                                                                                                                                                                                                            |

### 33.4.2.2 Target IP (TIP) Packet

**Table 33-17. IP Packet Definition**

| Name          | Target IP (TIP) Packet                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                     |                                                                                                                                                                       |   |   |   |   |   |  |  |  |  |   |   |   |   |   |   |   |   |  |  |   |         |  |  |   |   |   |   |   |  |  |   |               |  |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |

| Description   | Provides the target for some control flow transfers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                     |                                                                                                                                                                       |   |   |   |   |   |  |  |  |  |   |   |   |   |   |   |   |   |  |  |   |         |  |  |   |   |   |   |   |  |  |   |               |  |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |
| Application   | Anytime a TIP is encountered, it indicates that control was transferred to the IP provided in the payload.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                     |                                                                                                                                                                       |   |   |   |   |   |  |  |  |  |   |   |   |   |   |   |   |   |  |  |   |         |  |  |   |   |   |   |   |  |  |   |               |  |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |
|               | The source of this control flow change, and hence the IP or instruction to which it binds, depends on the packets that precede the TIP. If a TIP is encountered and all preceding packets have already been bound, then the TIP will apply to the upcoming indirect branch, far branch, or VMRESUME. However, if there was a preceding FUP that remains unbound, it will bind to the TIP. Here, the TIP provides the target of an asynchronous event or TSX abort that occurred at the IP given in the FUP payload. Note that there may be other packets, in addition to the FUP, which will bind to the TIP packet. See the packet application descriptions for other packets for details.                                                                                                        |                     |                                                                                                                                                                       |   |   |   |   |   |  |  |  |  |   |   |   |   |   |   |   |   |  |  |   |         |  |  |   |   |   |   |   |  |  |   |               |  |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |  |

**NOTES:**

- EENTER, EEXIT, ERESUME, AEX would be possible only for a debug enclave.

### IP Compression

The IP payload in a TIP, FUP, TIP.PGE, or TIP.PGD packet can vary in size, based on the mode of execution, and the use of IP compression. IP compression is an optional compression technique the processor may choose to employ to reduce bandwidth. With IP compression, the IP to be represented in the payload is compared with the last IP sent out, via any of FUP, TIP, TIP.PGE, or TIP.PGD. If that previous IP had the same upper (most significant) address bytes, those matching bytes may be suppressed in the current packet. The processor maintains an internal state of the "Last IP" that was encoded in trace packets, thus the decoder will need to keep track of the "Last IP" state in

software, to match fidelity with packets generated by hardware. "Last IP" is initialized to zero, hence if the first IP in the trace may be compressed if the upper bytes are zeroes.

The "IPBytes" field of the IP packets (FUP, TIP, TIP.PGE, TIP.PGD) serves to indicate how many bytes of payload are provided, and how the decoder should fill in any suppressed bytes. The algorithm for reconstructing the IP for a TIP/FUP packet is shown in the table below.

**Table 33-18. FUP/TIP IP Reconstruction**

| IPBytes | Uncompressed IP Value      |       |                  |       |                  |                  |      |     |  |  |  |  |  |  |  |  |  |  |  |  |  |
|---------|----------------------------|-------|------------------|-------|------------------|------------------|------|-----|--|--|--|--|--|--|--|--|--|--|--|--|--|
|         | 63:56                      | 55:48 | 47:40            | 39:32 | 31:24            | 23:16            | 15:8 | 7:0 |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 000b    | None, IP is out of context |       |                  |       |                  |                  |      |     |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 001b    | Last IP[63:16]             |       |                  |       |                  | IP Payload[15:0] |      |     |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 010b    | Last IP[63:32]             |       |                  |       | IP Payload[31:0] |                  |      |     |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 011b    | IP Payload[47] extended    |       | IP Payload[47:0] |       |                  |                  |      |     |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 100b    | Last IP [63:48]            |       | IP Payload[47:0] |       |                  |                  |      |     |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 101b    | Reserved                   |       |                  |       |                  |                  |      |     |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 110b    | IP Payload[63:0]           |       |                  |       |                  |                  |      |     |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 111b    | Reserved                   |       |                  |       |                  |                  |      |     |  |  |  |  |  |  |  |  |  |  |  |  |  |

The processor-internal Last IP state is guaranteed to be reset to zero when a PSB is sent out. This means that the IP that follows the PSB will either be un-compressed (011b or 110b, see Table 33-18), or compressed against zero.

At times, "IPbytes" will have a value of 0. As shown above, this does not mean that the IP payload matches the full address of the last IP, but rather that the IP for this packet was suppressed. This is used for cases where the IP that applies to the packet is out of context. An example is the TIP.PGD sent on a SYSCALL, when tracing only USR code. In that case, no TargetIP will be included in the packet, since that would expose an instruction point at CPL = 0. When the IP payload is suppressed in this manner, Last IP is not cleared, and instead refers to the last IP packet with a non-zero IPBytes field.

On processors that support a maximum linear address size of 32 bits, IP payloads may never exceed 32 bits (IPBytes <= 010b).

### Indirect Transfer Compression for Returns (RET)

In addition to IP compression, TIP packets for near return (RET) instructions can also be compressed. If the RET target matches the next IP of the corresponding CALL, then the TIP packet is unneeded, since the decoder can deduce the target IP by maintaining a CALL/RET stack of its own.

When a RET is compressed, a Taken indication is added to the TNT buffer. Because the RET generates no TIP packet, it also does not update the internal Last IP value, and thus the decoder should treat it the same way. If the RET is not compressed, it will generate a TIP packet (just like when RET compression is disabled, via IA32\_RTIT\_CTL.DisRETC).

A CALL/RET stack can be maintained by the decoder by doing the following:

1. Allocate space to store 64 RET targets.
2. For near CALLs, push the Next IP onto the stack. Once the stack is full, new CALLs will force the oldest entry off the end of the stack, such that only the youngest 64 entries are stored. Note that this excludes zero-length CALLs, which are direct near CALLs with displacement zero (to the next IP). These CALLs typically don't have matching RETs.
3. For near RETs, pop the top (youngest) entry off the stack. This will be the expected target of the RET.

In cases where a RET is compressed, the RET target is guaranteed to match the expected target from 3) above. If the target is not compressed, a TIP packet will be generated with the RET target, which may differ from the expected target in some cases.

The hardware ensures that packets read by the decoder will always have seen the CALL that corresponds to any compressed RET. The processor will never compress a RET across a PSB, a buffer overflow, or scenario where PacketEn=0. This means that a RET whose corresponding CALL executed while PacketEn=0, or before the last PSB, etc., will not be compressed.

If the CALL/RET stack is manipulated or corrupted by software, and thereby causes a RET to transfer control to a target that is inconsistent with the CALL/RET stack, then the RET will not be compressed, and will produce a TIP packet. This can happen, for example, if software executes a PUSH instruction to push a target onto the stack, and a later RET uses this target.

For processors that employ deferred TIPs (Section 33.4.2.3), an uncompressed RET will not be deferred, and hence will force out any accumulated TNTs or TIPs. This serves to avoid ambiguity, and make clear to the decoder whether the near RET was compressed, and hence a bit in the in-progress TNT should be consumed, or uncompressed, in which case there will be no in-progress TNT and thus a TIP should be consumed.

Note that in the unlikely case that a RET executes in a different execution mode than the associated CALL, the decoder will need to model the same behavior with its CALL stack. For instance, if a CALL executes in 64-bit mode, a 64-bit IP value will be pushed onto the software stack. If the corresponding RET executes in 32-bit mode, then only the lower 32 target bits will be popped off of the stack, which may mean that the RET does not go to the CALL's Next IP. This is architecturally correct behavior, and this RET could be compressed, thus the decoder should match this behavior.

### 33.4.2.3 Deferred TIPs

The processor may opt to defer sending out the TNT when TIPs are generated. Thus, rather than sending a partial TNT followed by a TIP, both packets will be deferred while the TNT accumulates more Jcc/RET results. Any number of TIP packets may be accumulated this way, such that only once the TNT is filled, or once another packet (e.g., FUP) is generated, the TNT will be sent, followed by all the deferred TIP packets, and finally terminated by the other packet(s) that forced out the TNT and TIP packets. Generation of many other packets (see list below) will force out the TNT and any accumulated TIP packets. This is an optional optimization in hardware to reduce the bandwidth consumption, and hence the performance impact, incurred by tracing.

**Table 33-19. TNT Examples with Deferred TIPs**

| Code Flow                                                                                                                                                                  | Packets, Non-Deferred TIPs            | Packets, Deferred TIPs                                                 |

| Dependencies  | PacketEn transitions to 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                 |   |   | Generation Scenario | Any branch instruction, control flow transfer, or MOV CR3 that sets PacketEn, a WRMSR that enables packet generation and sets PacketEn |   |   |   |  |  |  |  |  |  |
| Description   | <p>Indicates that PacketEn has transitioned to 1. It provides the IP at which the tracing begins. This can occur due to any of the enables that comprise PacketEn transitioning from 0 to 1, as long as all the others are asserted. Examples:</p> <ul style="list-style-type: none"> <li>▪ TriggerEn: This is set on software write to set IA32_RTIT_CTL.TraceEn as long as the Stopped and Error bits in IA32_RTIT_STATUS are clear. The IP payload will be the Next IP of the WRMSR.</li> <li>▪ FilterEn: This is set when software jumps into the tracing region. This region is defined by enabling IP filtering in IA32_RTIT_CTL.ADDRn_CFG, and defining the range in IA32_RTIT_ADDRn_[AB], see. Section 33.2.5.3. The IP payload will be the target of the branch.</li> <li>▪ ContextEn: This is set on a CPL change, a CR3 write or any other means of changing ContextEn. The IP payload will be the Next IP of the instruction that changes context if it is not a branch, otherwise it will be the target of the branch.</li> </ul> |                 |   |   |                     |                                                                                                                                        |   |   |   |  |  |  |  |  |  |
| Application   | TIP.PGE packets bind to the instruction at the IP given in the payload.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                 |   |   |                     |                                                                                                                                        |   |   |   |  |  |  |  |  |  |

### 33.4.2.5 Packet Generation Disable (TIP.PGD) Packet

**Table 33-21. TIP.PGD Packet Definition**

| Name          | Target IP - Packet Generation Disable (TIP.PGD) Packet                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                     |                                                                                                                                             |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |         |  |  |   |   |   |   |   |   |               |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |

| Dependencies  | PacketEn transitions to 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Generation Scenario | Any branch instruction, control flow transfer, or MOV CR3 that clears PacketEn, a WRMSR that disables packet generation and clears PacketEn |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |         |  |  |   |   |   |   |   |   |               |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |
| Description   | <p>Indicates that PacketEn has transitioned to 0. It will include the IP at which the tracing ends, unless ContextEn=0 or TraceEn=0 at the conclusion of the instruction or event that cleared PacketEn.</p> <p>PacketEn can be cleared due to any of the enables that comprise PacketEn transitioning from 1 to 0. Examples:</p> <ul style="list-style-type: none"> <li>▪ TriggerEn: This is cleared on software write to clear IA32_RTIT_CTL.TraceEn, or when IA32_RTIT_STATUS.Stopped is set, or on operational error. The IP payload will be suppressed in this case, and the "IPBytes" field will have the value 0.</li> <li>▪ FilterEn: This is cleared when software jumps out of the tracing region. This region is defined by enabling IP filtering in IA32_RTIT_CTL.ADDRn_CFG, and defining the range in IA32_RTIT_ADDRn_[AB], see, Section 33.2.5.3. The IP payload will depend on the type of the branch. For conditional branches, the payload is suppressed (IPBytes = 0), and in this case the destination can be inferred from the disassembly. For any other type of branch, the IP payload will be the target of the branch.</li> <li>▪ ContextEn: This can happen on a CPL change, a CR3 write or any other means of changing ContextEn. See Section 33.2.5.3 for details. In this case, when ContextEn is cleared, there will be no IP payload. The "IPBytes" field will have value 0.</li> </ul> <p>Note that, in cases where a branch that would normally produce a TIP packet (i.e., far transfer, indirect branch, interrupt, etc) or TNT update (conditional branch or compressed RT) causes PacketEn to transition from 1 to 0, the TIP or TNT bit will be replaced with TIP.PGD. The payload of the TIP.PGD will be the target of the branch, unless the result of the instruction causes TraceEn or ContextEn to be cleared (ie, SYSCALL when IA32_RTIT_CTL.OS=0). In the case where a conditional branch clears FilterEn and hence PacketEn, there will be no TNT bit for this branch, replaced instead by the TIP.PGD.</p> |                     |                                                                                                                                             |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |         |  |  |   |   |   |   |   |   |               |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |
| Application   | <p>TIP.PGD can be produced by any branch instructions, as well as some non-branch instructions, that clear PacketEn. When produced by a branch, it replaces any TIP or TNT update that the branch would normally produce.</p> <p>In cases where there is an unbound FUP preceding the TIP.PGD, then the TIP.PGD is part of compound operation (i.e., asynchronous event or TSX abort) which cleared PacketEn. For most such cases, the TIP.PGD is simply replacing a TIP, and should be treated the same way. The TIP.PGD may or may not have an IP payload, depending on whether the operation cleared ContextEn.</p> <p>If there is not an associated FUP, the binding will depend on whether there is an IP payload. If there is an IP payload, then the TIP.PGD should be applied to either the next direct branch whose target matches the TIP.PGD payload, or the next branch that would normally generate a TIP or TNT packet. If there is no IP payload, then the TIP.PGD should apply to the next branch or MOV CR3 instruction.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                     |                                                                                                                                             |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |         |  |  |   |   |   |   |   |   |               |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |   |                 |  |  |  |  |  |  |  |  |

### 33.4.2.6 Flow Update (FUP) Packet

**Table 33-22. FUP Packet Definition**

| Name          | Flow Update (FUP) Packet                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                     |                                                                                                                                                                                                                                                 |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |         |  |  |   |   |   |   |   |   |         |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |

| Dependencies  | TriggerEn && ContextEn.<br>(Typically depends on BranchEn and FilterEn as well, see Section 33.2.5, Section 33.4.2.21, and Section 33.4.2.22 for details.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Generation Scenario | Asynchronous Events (interrupts, exceptions, INIT, SIPI, SMI, VM exit, #MC), PSB+, XBEGIN, XEND, XABORT, XACQUIRE, XRELEASE, EENTER, EEXIT, ERESUME, EEE, AEX, <sup>1</sup> , INTO, INT1, INT3, INT n, a WRMSR that disables packet generation. |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |         |  |  |   |   |   |   |   |   |         |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |
| Description   | Provides the source address for asynchronous events, and some other instructions. Is never sent alone, always sent with an associated TIP or MODE packet, and potentially others.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                     |                                                                                                                                                                                                                                                 |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |         |  |  |   |   |   |   |   |   |         |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |
| Application   | <p>FUP packets provide the IP to which they bind. However, they are never standalone, but are coupled with other packets.</p> <p>In TSX cases, the FUP is immediately preceded by a MODE.TSX, which binds to the same IP. A TIP will follow only in the case of TSX aborts, see Section 33.4.2.8 for details.</p> <p>Otherwise, FUPs are part of compound packet events (see Section 33.4.1). In these compound cases, the FUP provides the source IP for an instruction or event, while a following TIP (or TIP.PGD) packet will provide the destination IP. Other packets may be included in the compound event between the FUP and TIP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                     |                                                                                                                                                                                                                                                 |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |         |  |  |   |   |   |   |   |   |         |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |

**NOTES:**

1. EENTER, EEXIT, ERESUME, EEE, AEX apply only if Intel Software Guard Extensions is supported.

#### FUP IP Payload

Flow Update Packet gives the source address of an instruction when it is needed. In general, branch instructions do not need a FUP, because the source address is clear from the disassembly. For asynchronous events, however, the source address cannot be inferred from the source, and hence a FUP will be sent. Table 33-23 illustrates cases where FUPs are sent, and which IP can be expected in those cases.

**Table 33-23. FUP Cases and IP Payload**

| Event                                                                    | Flow Update IP                                                         | Comment                                                                                                                                                                  |
|--------------------------------------------------------------------------|------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| External Interrupt, NMI/SMI, Traps, Machine Check (trap-like), INIT/SIPI | Address of next instruction (Next IP) that would have been executed    | Functionally, this matches the LBR FROM field value and also the EIP value which is saved onto the stack.                                                                |
| Exceptions/Faults, Machine check (fault-like)                            | Address of the instruction which took the exception/fault (Current IP) | This matches the similar functionality of LBR FROM field value and also the EIP value which is saved onto the stack.                                                     |
| Software Interrupt                                                       | Address of the software interrupt instruction (Current IP)             | This matches the similar functionality of LBR FROM field value, but does not match the EIP value which is saved onto the stack (Next Linear Instruction Pointer - NLIP). |
| EENTER, EEXIT, ERESUME, Enclave Exiting Event (EEE), AEX <sup>1</sup>    | Current IP of the instruction                                          | This matches the LBR FROM field value and also the EIP value which is saved onto the stack.                                                                              |
| XACQUIRE                                                                 | Address of the X* instruction                                          |                                                                                                                                                                          |
| XRELEASE, XBEGIN, XEND, XABORT, other transactional abort                | Current IP                                                             |                                                                                                                                                                          |
| #SMI                                                                     | IP that is saved into SMRAM                                            |                                                                                                                                                                          |
| WRMSR that clears TraceEn, PSB+                                          | Current IP                                                             |                                                                                                                                                                          |

**NOTES:**

1. Information on EENTER, EEXIT, ERESUME, EEE, Asynchronous Enclave eXit (AEX) can be found in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3D.

On a canonical fault due to sequentially fetching an instruction in non-canonical space (as opposed to jumping to non-canonical space), the IP of the fault (and thus the payload of the FUP) will be a non-canonical address. This is consistent with what is pushed on the stack for such faulting cases.

If there are post-commit task switch faults, the IP value of the FUP will be the original IP when the task switch started. This is the same value as would be seen in the LBR\_FROM field. But it is a different value as is saved on the stack or VMCS.

### 33.4.2.7 Paging Information (PIP) Packet

**Table 33-24. PIP Packet Definition**

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |   |                     |                                                           |   |   |   |         |  |  |  |  |  |

| Description   | <p>The CR3 payload shown includes only the address portion of the CR3 value. For PAE paging, CR3[11:5] are thus included. For other paging modes (32-bit and 4-level paging<sup>1</sup>), these bits are 0.</p> <p>This packet holds the CR3 address value. It will be generated on operations that modify CR3:</p> <ul style="list-style-type: none"> <li>▪ MOV CR3 operation</li> <li>▪ Task Switch</li> <li>▪ INIT and SIPI</li> <li>▪ VM exit, if “conceal VMX from PT” VM-exit control is 0 (see Section 33.5.1)</li> <li>▪ VM entry, if “conceal VMX from PT” VM-entry control is 0</li> </ul> <p>PIPs are not generated, despite changes to CR3, on SMI and RSM. This is due to the special behavior on these operations, see Section 33.2.9.3 for details. Note that, for some cases of task switch where CR3 is not modified, no PIP will be produced.</p> <p>The purpose of the PIP is to indicate to the decoder which application is running, so that it can apply the proper binaries to the linear addresses that are being traced.</p> <p>The PIP packet contains the new CR3 value when CR3 is written.</p> <p>PIPs generated by VM entries set the NR bit. PIPs generated in VMX non-root operation set the NR bit if the “conceal VMX from PT” VM-execution control is 0 (see Section 33.5.1). All other PIPs clear the NR bit.</p> |                |   |                     |                                                           |   |   |   |         |  |  |  |  |  |
| Application   | <p>The purpose of the PIP packet is to help the decoder uniquely identify what software is running at any given time. When a PIP is encountered, a decoder should do the following:</p> <ol style="list-style-type: none"> <li>1) If there was a prior unbound FUP (that is, a FUP not preceded by a packet such as MODE.TSX that consumes it, and it hence pairs with a TIP that has not yet been seen), then this PIP is part of a compound packet event (Section 33.4.1). Find the ending TIP and apply the new CR3/NR values to the TIP payload IP.</li> <li>2) Otherwise, look for the next MOV CR3, far branch, or VMRESUME/VMLAUNCH in the disassembly, and apply the new CR3 to the next (or target) IP.</li> </ol> <p>For examples of the packets generated by these flows, see Section 33.7.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |   |                     |                                                           |   |   |   |         |  |  |  |  |  |

**NOTES:**

1. Earlier versions of this manual used the term “IA-32e paging” to identify 4-level paging.

### 33.4.2.8 MODE Packets

MODE packets keep the decoder informed of various processor modes about which it needs to know in order to properly manage the packet output, or to properly disassemble the associated binaries. MODE packets include a header and a mode byte, as shown below.

**Table 33-25. General Form of MODE Packets**

|   |         |   |      |   |   |   |   |   |
|---|---------|---|------|---|---|---|---|---|
|   | 7       | 6 | 5    | 4 | 3 | 2 | 1 | 0 |
| 0 | 1       | 0 | 0    | 1 | 1 | 0 | 0 | 1 |
| 1 | Leaf ID |   | Mode |   |   |   |   |   |

The MODE Leaf ID indicates which set of mode bits are held in the lower bits.

### MODE.Exec Packet

**Table 33-26. MODE.Exec Packet Definition**

| Name                                                                                                                | MODE.Exec Packet                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                     |                                                                                                                                                                                                                                                                      |          |   |   |                        |                 |              |   |     |   |   |             |   |   |             |   |   |             |   |   |   |   |   |   |   |   |   |   |   |          |  |  |    |      |              |

| Description                                                                                                         | Indicates whether software is in 16, 32, or 64-bit mode, by providing the CS.D and (CS.L & IA32_EFER.LMA) values. Essential for the decoder to properly disassemble the associated binary. Further, if CPUID.0x14.0.EBX[6]=1 ("Event Trace Support"), it indicates when interrupts are masked by providing the RFLAGS.IF value.<br><br>MODE.Exec is sent at the time of a mode change, if dependencies are met at the time, otherwise it is sent when tracing resumes. In the former case, the MODE.Exec packet is generated along with other packets that result from the operation that changes the mode, and is guaranteed to be followed by a TIP or TIP.PGE for branch operations, or a FUP for non-branch operations (CLI, STI, or POPF if EventEn=1). In cases where the mode changes while filtering dependencies are not met, the processor ensures that the decoder doesn't lose track of the mode by sending any needed MODE.Exec once tracing resumes (preceding the TIP.PGE, if BranchEn=1). The processor may opt to suppress the MODE.Exec when tracing resumes if the mode matches that of the last MODE.Exec packet.<br>MODE.Exec packets are generated on CS.L, CS.D, or EFER.LMA changes only if control flow tracing is enabled (BranchEn=1). This is essential for the decoder to properly disassemble the associated binary. |                     |                                                                                                                                                                                                                                                                      |          |   |   |                        |                 |              |   |     |   |   |             |   |   |             |   |   |             |   |   |   |   |   |   |   |   |   |   |   |          |  |  |    |      |              |

| Description   | Indicates when a TSX transaction (either HLE or RTM) begins, commits, or aborts. Instructions executed transactionally will be “rolled back” if the transaction is aborted.                                                                                                                                                                                                                                                                                |      |                                                         |                     |   |                                                                                         |         |      |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |         |      |

| Application   | If PacketEn=1, MODE.TSX always immediately precedes a FUP. If the TXAbort bit is zero, then the mode change applies to the IP address in the payload of the FUP. If TXAbort=1, then the FUP will be followed by a TIP, and the mode change will apply to the IP address in the payload of the TIP.<br>MODE.TSX packets may be generated when PacketEn=0, due to FilterEn=0. In this case, only the last MODE.TSX generated before TIP.PGE need be applied. |      |                                                         |                     |   |                                                                                         |         |      |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |         |      |

| Description   | <p>Indicates when software has entered a user-configured TraceStop region. When the IP matches a TraceStop range while ContextEn and TriggerEn are set, a TraceStop action occurs. This disables tracing by setting IA32_RTIT_STATUS.Stopped, thereby clearing TriggerEn, and causes a TraceStop packet to be generated. The TraceStop action also forces FilterEn to 0. Note that TraceStop may not force a flush of internally buffered packets, and thus trace packet generation should still be manually disabled by clearing IA32_RTIT_CTL.TraceEn before examining output. See Section 33.2.5.3 for more details.</p> |   |   |                     |                                                                                                                                     |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| Application   | <p>If TraceStop follows a TIP.PGD (before the next TIP.PGE), then it was triggered either by the instruction that cleared PacketEn, or it was triggered by some later instruction that executed while FilterEn=0. In either case, the TraceStop can be applied at the IP of the TIP.PGD (if any). If TraceStop follows a TIP.PGE (before the next TIP.PGD), it should be applied at the last known IP.</p>                                                                                                                                                                                                                  |   |   |                     |                                                                                                                                     |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

| Description   | Indicates the core:bus ratio of the processor core. Useful for correlating wall-clock time and cycle time.                                                                                                                                                                                                                                                                                                                                                                                                            |   |   |                     |                                                                                                   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |                |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |  |
| Application   | The CBR packet indicates the point in the trace when a frequency transition has occurred. On some implementations, software execution will continue during transitions to a new frequency, while on others software execution ceases during frequency transitions. There is not a precise IP provided, to which to bind the CBR packet.                                                                                                                                                                               |   |   |                     |                                                                                                   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |                |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |  |

### 33.4.2.11 Timestamp Counter (TSC) Packet

**Table 33-30. TSC Packet Definition**

This may include P-state changes, wake from C-state, or clock modulation. Also on transition of TraceEn from 0 to 1. |   |   |   |   |   |  |  |  |  |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |             |  |  |  |  |  |  |  |  |  |   |              |  |  |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |  |  |
| Description   | When enabled by software, a TSC packet provides the lower 7 bytes of the current TSC value, as returned by the RDTSC instruction. This may be useful for tracking wall-clock time, and synchronizing the packets in the log with other timestamped logs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                     |                                                                                                                                                                                                                                     |   |   |   |   |   |  |  |  |  |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |             |  |  |  |  |  |  |  |  |  |   |              |  |  |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |  |  |
| Application   | TSC packet provides a wall-clock proxy of the event which generated it (packet generation enable, sleep state wake, etc). In all cases, TSC does not precisely indicate the time of any control flow packets; however, all preceding packets represent instructions that executed before the indicated TSC time, and all subsequent packets represent instructions that executed after it. There is not a precise IP to which to bind the TSC packet.                                                                                                                                                                                                                                                                        |                     |                                                                                                                                                                                                                                     |   |   |   |   |   |  |  |  |  |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |             |  |  |  |  |  |  |  |  |  |   |              |  |  |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |  |  |

| Description   | <p>When enabled by software, an MTC packet provides a periodic indication of wall-clock time. The 8-bit CTC (Common Timestamp Copy) payload value is set to (ART &gt;&gt; N) &amp; FFH. The frequency of the ART is related to the Maximum Non-Turbo frequency, and the ratio can be determined from CPUID leaf 15H, as described in Section 33.8.3. Software can select the threshold N, which determines the MTC frequency by setting the IA32_RTIT_CTL.MTCFreq field (see Section 33.2.8.2) to a supported value using the lookup enumerated by CPUID (see Section 33.3.1). See Section 33.8.3 for details on how to use the MTC payload to track TSC time.</p> <p>MTC provides 8 bits from the ART, starting with the bit selected by MTCFreq to dictate the frequency of the packet. Whenever that 8-bit range being watched changes, an MTC packet will be sent out with the new value of that 8-bit range. This allows the decoder to keep track of how much wall-clock time has elapsed since the last TSC packet was sent, by keeping track of how many MTC packets were sent and what their value was. The decoder can infer the truncated bits, CTC[N-1:0], are 0 at the time of the MTC packet.</p> <p>There are cases in which MTC packet can be dropped, due to overflow or other micro-architectural conditions. The decoder should be able to recover from such cases by checking the 8-bit payload of the next MTC packet, to determine how many MTC packets were dropped. It is not expected that &gt;256 consecutive MTC packets should ever be dropped.</p> |                     |                                                                           |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |            |  |  |  |  |  |  |  |
| Application   | MTC does not precisely indicate the time of any other packet, nor does it bind to any IP. However, all preceding packets represent instructions or events that executed before the indicated ART time, and all subsequent packets represent instructions that executed after, or at the same time as, the ART time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                     |                                                                           |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |            |  |  |  |  |  |  |  |

### 33.4.2.13 TSC/MTC Alignment (TMA) Packet

**Table 33-32. TMA Packet Definition**

| Name          | TSC/MTC Alignment (TMA) Packet                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                     |                           |   |   |   |   |   |       |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |          |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |   |   |                  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |       |

| Description   | The TMA packet serves to provide the information needed to allow the decoder to correlate MTC packets with TSC packets. With this packet, when a MTC packet is encountered, the decoder can determine how many timestamp counter ticks have passed since the last TSC or MTC packet. See Section 33.8.3.2 for details on how to make this calculation.                                                                                                                                                                                                                                                                                |                     |                           |   |   |   |   |   |       |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |          |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |   |   |                  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |       |
| Application   | TMA is always sent immediately following a TSC packet, and the payload values are consistent with the TSC payload value. Thus the application of TMA matches that of TSC.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                     |                           |   |   |   |   |   |       |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |          |  |  |  |  |  |  |  |   |           |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |   |   |                  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |       |

### 33.4.2.14 Cycle Count (CYC) Packet

**Table 33-33. Cycle Count Packet Definition**

| Name          | Cycle Count (CYC) Packet                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                     |                                                                                                                                        |   |   |     |   |   |  |  |   |   |   |   |   |   |   |   |   |                    |  |  |  |  |     |   |   |   |                     |  |  |  |  |     |  |  |   |                      |  |  |  |  |     |  |  |     |                                       |  |  |  |  |  |  |  |

See Section 33.3.6 for CYC-eligible packets. |   |   |     |   |   |  |  |   |   |   |   |   |   |   |   |   |                    |  |  |  |  |     |   |   |   |                     |  |  |  |  |     |  |  |   |                      |  |  |  |  |     |  |  |     |                                       |  |  |  |  |  |  |  |
| Description   | <p>The Cycle Counter field increments at the same rate as the processor core clock ticks, but with a variable length format (using a trailing EXP bit field) and a range-capped byte length. If the CYC value is less than 32, a 1-byte CYC will be generated, with Exp=0. If the CYC value is between 32 and 4095 inclusive, a 2-byte CYC will be generated, with byte 0 Exp=1 and byte 1 Exp=0. And so on. CYC provides the number of core clocks that have passed since the last CYC packet. CYC can be configured to be sent in every cycle in which an eligible packet is generated, or software can opt to use a threshold to limit the number of CYC packets, at the expense of some precision. These settings are configured using the IA32_RTIT_CTL.CycThresh field (see Section 33.2.8.2). For details on Cycle-Accurate Mode, IPC calculation, etc, see Section 33.3.6.</p> <p>When CycThresh=0, and hence no threshold is in use, then a CYC packet will be generated in any cycle in which any CYC-eligible packet is generated. The CYC packet will precede the other packets generated in the cycle, and provides the precise cycle time of the packets that follow.</p> <p>In addition to these CYC packets generated with other packets, CYC packets can be sent stand-alone. These packets serve simply to update the decoder with the number of cycles passed, and are used to ensure that a wrap of the processor's internal cycle counter doesn't cause cycle information to be lost. These stand-alone CYC packets do not indicate the cycle time of any other packet or operation, and will be followed by another CYC packet before any other CYC-eligible packet is seen.</p> <p>When CycThresh&gt;0, CYC packets are generated only after a minimum number of cycles have passed since the last CYC packet. Once this threshold has passed, the behavior above resumes, where CYC will either be sent in the next cycle that produces other CYC-eligible packets, or could be sent stand-alone.</p> <p>When using CYC thresholds, only the cycle time of the operation (instruction or event) that generates the CYC packet is truly known. Other operations simply have their execution time bounded: they completed at or after the last CYC time, and before the next CYC time.</p> |                     |                                                                                                                                        |   |   |     |   |   |  |  |   |   |   |   |   |   |   |   |   |                    |  |  |  |  |     |   |   |   |                     |  |  |  |  |     |  |  |   |                      |  |  |  |  |     |  |  |     |                                       |  |  |  |  |  |  |  |
| Application   | <p>CYC provides the offset cycle time (since the last CYC packet) for the CYC-eligible packet that follows. If another CYC is encountered before the next CYC-eligible packet, the cycle values should be accumulated and applied to the next CYC-eligible packet.</p> <p>If a CYC packet is generated by a TNT, note that the cycle time provided by the CYC packet applies to the first branch in the TNT packet.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                     |                                                                                                                                        |   |   |     |   |   |  |  |   |   |   |   |   |   |   |   |   |                    |  |  |  |  |     |   |   |   |                     |  |  |  |  |     |  |  |   |                      |  |  |  |  |     |  |  |     |                                       |  |  |  |  |  |  |  |

### 33.4.2.15 VMCS Packet

**Table 33-34. VMCS Packet Definition**

| Name          | VMCS Packet                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                     |                                                                                                                                 |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |                      |  |  |  |  |  |  |  |   |                      |  |  |  |  |  |  |  |   |                      |  |  |  |  |  |  |  |   |                      |  |  |  |  |  |  |  |   |                      |  |  |  |  |  |  |  |

| Description   | <p>The VMCS packet provides a VMCS pointer for a decoder to determine the transition of code contexts:</p> <ul style="list-style-type: none"> <li>On a successful VMPTRLD (i.e., a VMPTRLD that doesn't fault, fail, or VM exit), the VMCS packet contains the logical processor's VMCS pointer established by VMPTRLD (for subsequent execution of a VM guest context).</li> <li>An SMM VM exit loads the logical processor's VMCS pointer with the SMM-transfer VMCS pointer. If the "conceal VMX from PT" VM-exit control is 0 (see Section 33.5.1), a VMCS packet provides this pointer. See Section 33.6 on tracing inside and outside STM.</li> <li>A VM entry that returns from SMM loads the logical processor's VMCS pointer from a field in the SMM-transfer VMCS. If the "conceal VMX from PT" VM-entry control is 0, a VMCS packet provides this pointer. Whether the VM entry is to VMX root operation or VMX non-root operation is indicated by the PIP.NR bit.</li> </ul> <p>A VMCS packet generated before a VMCS pointer has been loaded, or after the VMCS pointer has been cleared will set all 64 bits in the VMCS pointer field.</p> <p>VMCS packets will not be seen on processors with IA32_VMX_MISC[bit 14]=0, as these processors do not allow TraceEn to be set in VMX operation.</p> |                     |                                                                                                                                 |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |                      |  |  |  |  |  |  |  |   |                      |  |  |  |  |  |  |  |   |                      |  |  |  |  |  |  |  |   |                      |  |  |  |  |  |  |  |   |                      |  |  |  |  |  |  |  |
| Application   | <p>The purpose of the VMCS packet is to help the decoder uniquely identify changes in the executing software context in situations that CR3 may not be unique.</p> <p>When a VMCS packet is encountered, a decoder should do the following:</p> <ul style="list-style-type: none"> <li>If there was a prior unbound FUP (that is, a FUP not preceded by a packet such as MODE.TSX that consumes it, and it hence pairs with a TIP that has not yet been seen), then this VMCS is part of a compound packet event (Section 33.4.1). Find the ending TIP and apply the new VMCS base pointer value to the TIP payload IP.</li> <li>Otherwise, look for the next VMPTRLD, VMRESUME, or VMLAUNCH in the disassembly, and apply the new VMCS base pointer on the next VM entry.</li> </ul> <p>For examples of the packets generated by these flows, see Section 33.7.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                            |                     |                                                                                                                                 |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |                      |  |  |  |  |  |  |  |   |                      |  |  |  |  |  |  |  |   |                      |  |  |  |  |  |  |  |   |                      |  |  |  |  |  |  |  |   |                      |  |  |  |  |  |  |  |

### 33.4.2.16 Overflow (OVF) Packet

| Description   | OVF simply indicates to the decoder that an internal buffer overflow occurred, and packets were likely lost. If BranchEN= 1, OVF is followed by a FUP or TIP.PGE which will provide the IP at which packet generation resumes. See Section 33.3.8.                                                                                                                                                                                                                           |   |                     |                                           |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| Application   | When an OVF packet is encountered, the decoder should skip to the IP given in the subsequent FUP or TIP.PGE. The cycle counter for the CYC packet will be reset at the time the OVF packet is sent. Software should reset its call stack depth on overflow, since no RET compression is allowed across an overflow. Similarly, any IP compression that follows the OVF is guaranteed to use as a reference LastIP the IP payload of an IP packet that preceded the overflow. |   |                     |                                           |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

### 33.4.2.17 Packet Stream Boundary (PSB) Packet

Table 33-36. PSB Packet Definition

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |    |   |   |   |   |   |   |   |   |    |   |   |   |   |   |   |   |   |    |   |   |   |   |   |   |   |   |    |   |   |   |   |   |   |   |   |    |   |   |   |   |   |   |   |   |    |   |   |   |   |   |   |   |   |

PSB is sent when IA32_RTIT_STATUS.PacketByteCnt=0, and each time it crosses the software selected threshold after that. May be sent for other micro-architectural conditions as well. |
| Description  | PSB is a unique pattern in the packet output log, and hence serves as a sync point for the decoder. It is a pattern that the decoder can search for in order to get aligned on packet boundaries. This packet is periodic, based on the number of output bytes, as indicated by IA32_RTIT_STATUS.PacketByteCnt. The period is chosen by software, via IA32_RTIT_CTL.PSBFreq (see Section 33.2.8.2). Note, however, that the PSB period is not precise, it simply reflects the average number of output bytes that should pass between PSBs. The processor will make a best effort to insert PSB as quickly after the selected threshold is reached as possible. The processor also may send extra PSB packets for some micro-architectural conditions.<br>PSB also serves as the leading packet for a set of "status-only" packets collectively known as PSB+ (Section 33.3.7). |                     |                                                                                                                                                                                                                                                              |
| Application  | When a PSB is seen, the decoder should interpret all following packets as "status only", until either a PSBEND or OVF packet is encountered. "Status only" implies that the binding and ordering rules to which these packets normally adhere are ignored, and the state they carry can instead be applied to the IP payload in the FUP packet that is included.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                     |                                                                                                                                                                                                                                                              |

| Dependencies  | TriggerEn                                                                                                                                                                                                                                                                                                                                    |   |   | Generation Scenario | Always follows PSB packet, separated by PSB+ packets |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| Description   | PSBEND is simply a terminator for the series of "status only" (PSB+) packets that follow PSB (Section 33.3.7).                                                                                                                                                                                                                               |   |   |                     |                                                      |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| Application   | When a PSBEND packet is seen, the decoder should cease to treat packets as "status only".                                                                                                                                                                                                                                                    |   |   |                     |                                                      |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

| Dependencies  | TriggerEn                                                                                                                                                                     |                | Generation Scenario |   | Implementation specific. |   |   |   |   |  |  |  |  |  |  |  |
| Description   | This packet is generated by hardware, the payload meaning is model-specific.                                                                                                  |                |                     |   |                          |   |   |   |   |  |  |  |  |  |  |  |
| Application   | Unless a decoder has been extended for a particular family/model/stepping to interpret MNT packet payloads, this packet should simply be ignored. It does not bind to any IP. |                |                     |   |                          |   |   |   |   |  |  |  |  |  |  |  |

| Description                            | <p>This packet indicates that software execution has stopped due to processor clock powerdown. Later packets will indicate when execution resumes.</p> <p>If EXSTOP is generated while ContextEn is set, the IP bit will be set, and EXSTOP will be followed by a FUP packet containing the IP at which execution stopped. More precisely, this will be the IP of the oldest instruction that has not yet completed.</p> <p>This packet is CYC-eligible, and hence will generate a CYC packet if IA32_RTIT_CTL.CYCEn=1 and any CYC Threshold has been reached.</p> |   |   |                     |                                                                                                                                                                                                                                                                          |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |    |   |   |   |   |   |   |   |
| Application                            | <p>If a FUP follows EXSTOP (hence IP bit set), the EXSTOP can be bound to the FUP IP. Otherwise the IP is not known.</p> <p>Time of powerdown can be inferred from the preceding CYC, if CYCEn=1. Combined with the TSC at the time of wake (if TSCEn=1), this can be used to determine the duration of the powerdown.</p>                                                                                                                                                                                                                                         |   |   |                     |                                                                                                                                                                                                                                                                          |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |    |   |   |   |   |   |   |   |

### 33.4.2.23 MWAIT Packet

**Table 33-42. MWAIT Packet Definition**

| Name          | MWAIT Packet                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                     |                                                                                                            |   |   |   |   |   |          |  |  |  |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |                  |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |          |  |   |          |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |  |  |

| Description   | <p>Indicates that an MWAIT operation to C-state deeper than C0.0 completed. The MWAIT hints and extensions passed in by software are exposed in the payload. For UMWAIT and TPAUSE, the EXT field holds the input register value that determines the optimized state requested.</p> <p>For entry to some highly optimized C0 sub-C-states, such as C0.1, no MWAIT packet is generated.</p> <p>This packet is CYC-eligible, and hence will generate a CYC packet if IA32_RTIT_CTL.CYCEn=1 and any CYC Threshold has been reached.</p>                                                                                                                                                                                                                                                                                                                                    |                     |                                                                                                            |   |   |   |   |   |          |  |  |  |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |                  |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |          |  |   |          |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |  |  |
| Application   | The binding for the upcoming EXSTOP packet also applies to the MWAIT packet. See Section 33.4.2.22.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                     |                                                                                                            |   |   |   |   |   |          |  |  |  |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |                  |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |          |  |   |          |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |  |  |   |          |  |  |  |  |  |  |  |  |  |

### 33.4.2.24 Power Entry (PWRE) Packet

| <p>Description</p> <p>Indicates processor entry to the resolved thread C-state and sub C-state indicated. The processor will remain in this C-state until either another PWRE indicates the processor has moved to a C-state deeper than C0.0, or a PWRX packet indicates a return to C0.0.</p> <p>For entry to some highly optimized C0 sub-C-states, such as C0.1, no PWRE packet is generated.</p> <p>Note that some CPUs may allow MWAIT to request a deeper C-state than is supported by the core. These deeper C-states may have platform-level implications that differentiate them. However, the PWRE packet will provide only the resolved thread C-state, which will not exceed that supported by the core.</p> <p>If the C-state entry was initiated by hardware, rather than a direct software request (such as MWAIT, UMWAIT, TPAUSE, HLT, or shutdown), the Hw bit will be set to indicate this. Hardware Duty Cycling (see Section 15.5, “Hardware Duty Cycling (HDC)” in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3B) is an example of such a case.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |          |                       |                     |                                           |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |    |          |  |  |  |  |  |  |   |                         |  |  |  |                             |  |  |  |  |
| <p>Application</p> <p>When transitioning from C0.0 to a deeper C-state, the PWRE packet will be followed by an EXSTOP. If that EXSTOP packet has the IP bit set, then the following FUP will provide the IP at which the C-state entry occurred. Subsequent PWRE packets generated before the next PWRX should bind to the same IP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |          |                       |                     |                                           |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |    |          |  |  |  |  |  |  |   |                         |  |  |  |                             |  |  |  |  |

### 33.4.2.25 Power Exit (PWRX) Packet

**Table 33-44. PWRX Packet Definition**

| Name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | PWRX Packet                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |  |  |  |  |  |  |  |  |  |     |       |         |   |           |                                          |   |                |                                                                 |   |                            |                                         |   |         |                                                         |             |                                                                                                                                        |  |  |  |  |  |  |  |  |  |
| <p>Description</p> <p>Indicates processor return to thread C0 from a C-state deeper than C0.0. For return from some highly optimized C0 sub-C-states, such as C0.1, no PWRX packet is generated. The Last Core C-State field provides the MWAIT encoding for the core C-state at the time of the wake. The Deepest Core C-State provides the MWAIT encoding for the deepest core C-state achieved during the sleep session, or since leaving thread C0. MWAIT encodings for C-states can be found in Table 4-11 in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B. Note that these values reflect only the core C-state, and hence will not exceed the maximum supported core C-state, even if deeper C-states can be requested. The Wake Reason field is one-hot, encoded as follows:</p> <table border="1"> <thead> <tr> <th>Bit</th><th>Field</th><th>Meaning</th></tr> </thead> <tbody> <tr> <td>0</td><td>Interrupt</td><td>Wake due to external interrupt received.</td></tr> <tr> <td>1</td><td>Timer Deadline</td><td>Wake due to timer expiration, such as UMWAIT/TPAUSE TSC-quanta.</td></tr> <tr> <td>2</td><td>Store to Monitored Address</td><td>Wake due to store to monitored address.</td></tr> <tr> <td>3</td><td>HW Wake</td><td>Wake due to hardware autonomous condition, such as HDC.</td></tr> </tbody> </table> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                 |                       |                     |                                                   |   |   |   |   | Bit | Field | Meaning | 0 | Interrupt | Wake due to external interrupt received. | 1 | Timer Deadline | Wake due to timer expiration, such as UMWAIT/TPAUSE TSC-quanta. | 2 | Store to | Application   | <p>A BBP will always be followed by a Block End Packet (BEP), and when the block is generated while ContextEn=1 that BEP will have IP=1 and be followed by a FUP that provides the IP to which the block should be bound. Note that, in addition to BEP, a block can be terminated by a BBP (indicating the start of a new block) or an OVF packet.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |          |                     |                                           |           |   |   |   |  |          |            |      |          |      |                           |            |          |      |            |      |             |            |          |      |             |      |             |      |             |            |          |      |               |            |          |   |   |    |          |  |  |           |  |  |  |  |

| Description   | The size of the BIP payload is determined by the Size field in the preceding BBP packet. The BIP header provides the ID value that, when combined with the Type field from the preceding BBP, uniquely identifies the state value held in the BIP payload. See Table 33-47 below for the complete list.                                                                                                                                                                                                                                                                                                                                                           |                     |          |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |         |  |  |  |  |   |   |   |   |              |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |

#### BIP State Value Encodings

The table below provides the encoding values for all defined block items. State items that are larger than 8 bytes, such as XMM register values, are broken into multiple 8-byte components. BIP packets with Size=1 (4 byte payload) will provide only the lower 4 bytes of the associated state value.

**Table 33-47. BIP Encodings**

| BBP.Type                  | BIP.ID | State Value |
|---------------------------|--------|-------------|
| General-Purpose Registers |        |             |
| 0x01                      | 0x00   | R/EFLAGS    |
| 0x01                      | 0x01   | R/EIP       |
| 0x01                      | 0x02   | R/EAX       |
| 0x01                      | 0x03   | R/ECX       |

**Table 33-47. BIP Encodings (Contd.)**

| BBP.Type                              | BIP.ID | State Value         |
|---------------------------------------|--------|---------------------|
| 0x01                                  | 0x04   | R/EDX               |

| Description   | Indicates the end of a packet block. The IP bit indicates if a FUP will follow, and will be set if ContextEn=1.                                                                                                                                                                                                                                                                           |   |   |                     |          |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |    |   |   |   |   |   |   |   |
| Application   | The block, from initial BBP to the BEP, binds to the FUP IP, if IP=1, and consumes the FUP.                                                                                                                                                                                                                                                                                               |   |   |                     |          |   |   |   |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |    |   |   |   |   |   |   |   |

### 33.4.2.29 Control Flow Event (CFE) Packet

**Table 33-49. Control Flow Event Packet Definition**

|               | IP bit indicates if a stand-alone FUP will follow.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                     |                                                                                                                                                                                                                                                                                            |           |   |   |   |   |  |  |  |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |    |          |  |           |  |  |  |  |  |  |   |             |  |  |  |  |  |  |  |  |  |
| Dependencies  | IA32_RTIT_CTL.EventEn && TriggerEn && ContextEn<br>On ContextEn transitions, the CFE will be generated regardless of direction (1→0 or 0→1). VM exit is an exception, where CFE.VMEXIT depends only on the prior value of ContextEn.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Generation Scenario | Software interrupt, external interrupt, user interrupt, or exception, including those injected on VM entry.<br>INIT, SIPI, SMI, RSM, IRET, Shutdown.<br>VM exit, if "Conceal VMX in PT" VMCS exit control is 0.<br>VM entry, if "Conceal VMX in PT" VMCS entry control is 0.<br>TSX Abort. |           |   |   |   |   |  |  |  |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |    |          |  |           |  |  |  |  |  |  |   |             |  |  |  |  |  |  |  |  |  |
| Description   | This packet indicates that an asynchronous event or related event (see list above) has occurred. The type of event is provided in the packet (see Table 33-50 below), and, if the IP bit is set, the IP at which the event occurred is provided in a stand-alone FUP packet that follows. Further, in the case of an interrupt or exception, the vector field provides the vector of the event.<br>The IP bit will be set only when ContextEn=1 before the event is taken, and either BranchEn=0 or else no FUP is generated for this event by BranchEn=1. There are some cases, such as SIPI and RSM, where no FUP is generated. Note that events that are not delivered to software, such as nested events or events which cause a VM exit, do not generate CFE packets. |                     |                                                                                                                                                                                                                                                                                            |           |   |   |   |   |  |  |  |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |    |          |  |           |  |  |  |  |  |  |   |             |  |  |  |  |  |  |  |  |  |
| Application   | If the IP bit is set, a FUP will follow that is stand-alone (not part of a compound packet event), and the CFE consumes the FUP. If the IP bit is not set, the CFE binds to the next FUP if PacketEn=1 (hence the CFE comes after a TIP.PGE but before the next TIP.PGD), and is stand-alone if PacketEn=0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                     |                                                                                                                                                                                                                                                                                            |           |   |   |   |   |  |  |  |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |    |          |  |           |  |  |  |  |  |  |   |             |  |  |  |  |  |  |  |  |  |

#### CFE Packet Type and Vector Fields

Every CFE has a Type field, which provides the type of event which generated the packet. For a subset of CFE Types, the CFE.Vector field may be valid. Details on these fields, as well as the IP to be expected in any following FUP packet, are provided in the table below.

**Table 33-50. CFE Packet Type and Vector Fields Details**

| CFE Subtype | Type | Vector       | FUP IP | Details                                                                                                                                                                                     |
|-------------|------|--------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INTR        | 0x1  | Event Vector | Varies | Used for interrupts (external and software), Exceptions, Faults, and NMI. FUP contains the address of the instruction that has not completed (NLIP for trap events, CLIP for fault events). |
| IRET        | 0x2  | Invalid      | CLIP   |                                                                                                                                                                                             |
| SMI         | 0x3  | Invalid      | NLIP   |                                                                                                                                                                                             |
| RSM         | 0x4  | Invalid      | None   |                                                                                                                                                                                             |
| SIPI        | 0x5  | SIPI Vector  | None   |                                                                                                                                                                                             |
| INIT        | 0x6  | Invalid      | NLIP   |                                                                                                                                                                                             |
| VMENTRY     | 0x7  | Invalid      | CLIP   | FUP contains IP of VMLAUNCH/VMRESUME.                                                                                                                                                       |

**Table 33-50. CFE Packet Type and Vector Fields Details (Contd.)**

| CFE Subtype | Type       | Vector                | FUP IP | Details                                                                                                                                                                                                    |
|-------------|------------|-----------------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VMEXIT      | 0x8        | Invalid               | Varies | FUP IP varies depending on type of VM exit, but will be the address of the instruction that has not completed. Will be consistent with Guest IP saved in VMCS.                                             |
| VMEXIT_INTR | 0x9        | Event Vector          | Varies | Sent in cases where VM exit was caused by an INTR event (interrupt, exception, fault, or NMI). Vector provided is for the event which caused the VM exit. FUP IP behavior matches that of INTR type above. |
| SHUTDOWN    | 0xa        | Invalid               | Varies | FUP IP varies depending on the type of event that caused shutdown, but will be the address of the instruction that has not completed.                                                                      |
| Reserved    | 0xb        | N/A                   | N/A    |                                                                                                                                                                                                            |
| UINTR       | 0xc        | User Interrupt Vector | NLIP   | User interrupt delivered.                                                                                                                                                                                  |
| UIRET       | 0xd        | Invalid               | CLIP   | Exiting from user interrupt routine.                                                                                                                                                                       |
| Reserved    | 0xe...0x1f | N/A                   | N/A    | Reserved                                                                                                                                                                                                   |

### 33.4.2.30 Event Data (EVD) Packet

**Table 33-51. Event Data Packet Definition**

| Name              | EVD                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                     |                                                                                                                      |   |   |   |   |   |  |  |      |         |         |                                              |         |                               |         |                        |                   |          |  |   |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |          |  |           |  |  |  |  |  |  |  |   |              |  |  |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |  |    |                |  |  |  |  |  |  |  |  |  |

| Application       | EVD packets bind to the same IP (if any) as the subsequent CFE packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                     |                                                                                                                      |   |   |   |   |   |  |  |      |         |         |                                              |         |                               |         |                        |                   |          |  |   |   |   |   |   |   |   |   |   |  |  |   |   |   |   |   |   |   |   |   |  |  |   |          |  |           |  |  |  |  |  |  |  |   |              |  |  |  |  |  |  |  |  |  |   |               |  |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |  |   |                |  |  |  |  |  |  |  |  |  |    |                |  |  |  |  |  |  |  |  |  |

## 33.5 TRACING IN VMX OPERATION

On processors that IA32\_VMX\_MISC[bit 14] reports 1, TraceEn can be set in VMX operation. The VMM can configure specific VMX controls to control what virtualization-specific data is included within the trace packets (see Section 33.5.1 for details). The VMM can also configure the VMCS to limit tracing to non-root operation, or to trace across both root and non-root operation. The VMCS controls exist to simplify virtualization of Intel PT for guest use, including the “Clear IA32\_RTIT\_CTL” exit control (See Section 25.7.1), “Load IA32\_RTIT\_CTL” entry control (See Section 25.8.1), and “Intel PT uses guest physical addresses” execution control (See Section 26.5.3).

For older processors that do not support these VMCS controls, the MSR-load areas used by VMX transitions can be employed by the VMM to restrict tracing to the desired context. See Section 33.5.2 for details. Tracing with SMM Transfer Monitor is described in Section 33.6.

### 33.5.1 VMX-Specific Packets and VMCS Controls

In all of the usages of VMX and Intel PT, a decoder in the host or VMM context can identify the occurrences of VMX transitions with the aid of VMX-specific packets. There are four kinds of packets relevant to VMX:

- **VMCS packet.** The VMX transitions of individual VMs can be distinguished by a decoder using the VMCS-pointer field in a VMCS packet. A VMCS packet is sent on a successful execution of VMPTRLD, and its VMCS-pointer field stores the VMCS pointer loaded by that execution. See Section 33.4.2.15 for details.
- **The NR (non-root) bit in a PIP packet.** Normally, the NR bit is set in any PIP packet generated in VMX non-root operation. In addition, PIP packets are generated with each VM entry and VM exit. Thus a transition of the NR bit from 0 to 1 indicates the occurrence of a VM entry, and a transition of 1 to 0 indicates the occurrence of a VM exit.
- **CFE packet.** Identifies VM exit and VM entry operations.
- **EVD packet.** Provides the exit reason and exit qualification for VM exits.

There are VMX controls that a VMM can set to conceal some of this VMX-specific information (by suppressing its recording) and thereby prevent it from leaking across virtualization boundaries. There is one of these controls (each of which is called “conceal VMX from PT”) of each type of VMX control.

**Table 33-52. VMX Controls For Intel Processor Trace**

| Type of VMX Control                            | Bit Position <sup>1</sup> | Value | Behavior                                                                                                                                                                                                                             |
|------------------------------------------------|---------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Secondary processor-based VM-execution control | 19                        | 0     | Each PIP generated in VM non-root operation will set the NR bit.<br>PSB+ in VMX non-root operation will include the VMCS packet, to ensure that the decoder knows which guest is currently in use.                                   |
|                                                |                           | 1     | Each PIP generated in VMX non-root operation will clear the NR bit.<br>PSB+ in VMX non-root operation will not include the VMCS packet.                                                                                              |
| VM-exit control                                | 24                        | 0     | Each VM exit generates a PIP in which the NR bit is clear, and a CFE/EVD if Event Trace is enabled.<br>In addition, SMM VM exits generate VMCS packets.                                                                              |
|                                                |                           | 1     | VM exits do not generate PIPs, CFEs, or EVDs, and no VMCS packets are generated on SMM VM exits.                                                                                                                                     |
| VM-entry control                               | 17                        | 0     | Each VM entry generates a PIP in which the NR bit is set (except VM entries that return from SMM to VMX root operation), and a CFE if Event Trace is enabled.<br>In addition, VM entries that return from SMM generate VMCS packets. |
|                                                |                           | 1     | VM entries do not generate PIPs or CFEs, and no VMCS packets are generated on VM entries that return from SMM.                                                                                                                       |

**NOTES:**

1. These are the positions of the control bits in the relevant VMX control fields.

The 0-settings of these VMX controls enable all VMX-specific packet information. The scenarios that would use these default settings also do not require the VMM to use VMX MSR-load areas to enable and disable trace-packet generation across VMX transitions.

If IA32\_VMX\_MISC[bit 14] reports 0, the 1-settings of the VMX controls in Table 33-52 are not supported, and VM entry will fail on any attempt to set them.

### 33.5.2 Managing Trace Packet Generation Across VMX Transitions

In tracing scenarios that collect packets for both VMX root operation and VMX non-root operation, a host executive can manage the MSRs associated with trace packet generation directly. The states of these MSRs need not be modified across VMX transitions.

For tracing scenarios that collect packets only within VMX root operation or only within VMX non-root operation, the VMM can toggle IA32\_RTIT\_CTL.TraceEn on VMX transitions.

### 33.5.2.1 System-Wide Tracing

When a host or VMM configures Intel PT to collect trace packets of the entire system, it can leave the relevant VMX controls clear to allow VMX-specific packets to provide information across VMX transitions.

The decoder will desire to identify the occurrence of VMX transitions. The packets of interests to a decoder are shown in Table 33-53.

**Table 33-53. Packets on VMX Transitions (System-Wide Tracing)**

| Event    | Packets                               | Enable              | Description                                                                                                                                                                                                                                                                                                                                        |
|----------|---------------------------------------|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VM exit  | EVD.VMXR,<br>EVD.VMXQ,<br>CFE.VMEXIT* | EventEn             | The CFE identifies the transfer as a VM exit, while the associated EVDs provide the exit reason and exit qualification.                                                                                                                                                                                                                            |
|          | FUP(GuestIP)                          | BranchEn or EventEn | The FUP indicates at which point in the guest flow the VM exit occurred. This is important, since VM exit can be an asynchronous event. The IP will match that written into the VMCS.                                                                                                                                                              |
|          | PIP(HostCR3, NR=0)                    |                     | The PIP packet provides the new host CR3 value, as well as indication that the logical processor is entering VMX root operation. This allows the decoder to identify the change of executing context from guest to host and load the appropriate set of binaries to continue decode.                                                               |
|          | TIP(HostIP)                           | BranchEn            | The TIP indicates the destination IP, the IP of the first instruction to be executed in VMX root operation.<br><br>Note, this packet could be preceded by a MODE.Exec packet (Section 33.4.2.8). This is generated only in cases where CS.D or (CS.L & EFER.LMA) change during the transition.                                                     |
| VM entry | CFEVMENTRY,<br>FUP(CLIP)              | EventEn             | The CFE identifies the transfer as a VM entry, while the FUP identifies the VMLAUNCH/VMRESUME IP.                                                                                                                                                                                                                                                  |
|          | PIP(GuestCR3, NR=1)                   | BranchEn            | The PIP packet provides the new guest CR3 value, as well as indication that the logical processor is entering VMX non-root operation. This allows the decoder to identify the change of executing context from host to guest and load the appropriate set of binaries to continue decode.                                                          |
|          | TIP(GuestIP)                          | BranchEn            | The TIP indicates the destination IP, the IP of the first instruction to be executed in VMX non-root operation. This should match the RIP loaded from the VMCS.<br><br>Note, this packet could be preceded by a MODE.Exec packet (Section 33.4.2.8). This is generated only in cases where CS.D or (CS.L & EFER.LMA) change during the transition. |

Since the VMX controls that suppress packet generation are cleared, a VMCS packet will be included in all PSB+ for this usage scenario. Additionally, VMPTRLD will generate such a packet. Thus the decoder can distinguish the execution context of different VMs.

When the host VMM configures a system to collect trace packets in this scenario, it should emulate CPUID to report CPUID.(EAX=07H, ECX=0):EBX[bit 26] as 0 to guests, indicating to guests that Intel PT is not available.

### VMX TSC Manipulation

The TSC packets generated while in VMX non-root operation will include any changes resulting from the use of a VMM's use of the TSC offsetting or TSC scaling VMX controls (see Chapter 26, "VMX Non-Root Operation"). In this system-wide usage model, the decoder may need to account for the effect of per-VM adjustments in the TSC packets generated in VMX non-root operation and the absence of TSC adjustments in TSC packets generated in VMX root operation. The VMM can supply this information to the decoder.

### 33.5.2.2 Guest-Only Tracing

A VMM can configure trace-packet generation while in VMX non-root operation for guests executing normally. This is accomplished by utilizing VMCS controls to manipulate the guest IA32\_RTIT\_CTL value on VMX transitions. For

older processors that do not support these VMCS controls, a VMM can use the VMX MSR-load areas on VM exits (see Section 25.7.2, “VM-Exit Controls for MSRs”) and VM entries (see Section 25.8.2, “VM-Entry Controls for MSRs”) to limit trace-packet generation to the guest environment.

For this usage, VM entry is programmed to enable trace packet generation, while VM exit is programmed to clear IA32\_RTIT\_CTL.TraceEn so as to disable trace-packet generation in the host. Further, if it is preferred that the guest packet stream contain no indication that execution was in VMX non-root operation, the VMM should set to 1 all the VMX controls enumerated in Table 33-52.

### 33.5.2.3 Emulation of Intel PT Traced State

If a VMM emulates an element of processor state by taking a VM exit on reads and/or writes to that piece of state, and the state element impacts Intel PT packet generation or values, it may be incumbent upon the VMM to insert or modify the output trace data.

If a VM exit is taken on a guest write to CR3 (including “MOV CR3” as well as task switches), the PIP packet normally generated on the CR3 write will be missing.

To avoid decoder confusion when the guest trace is decoded, the VMM should emulate the missing PIP by writing it into the guest output buffer. If the guest CR3 value is manipulated, the VMM may also need to manipulate the IA32\_RTIT\_CR3\_MATCH value, in order to ensure the trace behavior matches the guest's expectation.

Similarly, if a VMM emulates the TSC value by taking a VM exit on RDTSC, the TSC packets generated in the trace may mismatch the TSC values returned by the VMM on RDTSC. To ensure that the trace can be properly aligned with software logs based on RDTSC, the VMM should either make corresponding modifications to the TSC packet values in the guest trace, or use mechanisms such as TSC offsetting or TSC scaling in place of exiting.

### 33.5.2.4 TSC Scaling

When TSC scaling is enabled for a guest using Intel PT, the VMM should ensure that the value of Maximum Non-Turbo Ratio[15:8] in MSR\_PLATFORM\_INFO (MSR 0CEH) and the TSC/“core crystal clock” ratio (EBX/EAX) in CPUID leaf 15H are set in a manner consistent with the resulting TSC rate that will be visible to the VM. This will allow the decoder to properly apply TSC packets, MTC packets (based on the core crystal clock or ART, whose frequency is indicated by CPUID leaf 15H), and CBR packets (which indicate the ratio of the processor frequency to the Max Non-Turbo frequency). Absent this, or separate indication of the scaling factor, the decoder will be unable to properly track time in the trace. See Section 33.8.3 for details on tracking time within an Intel PT trace.

### 33.5.2.5 Failed VM Entry

The packets generated by a failed VM entry depend both on the VMCS configuration, as well as on the type of failure. The results to expect are summarized in the table below. Note that packets in *italics* may or may not be generated, depending on implementation choice, and the point of failure.

**Table 33-54. Packets on a Failed VM Entry**

| Usage Model | Entry Configuration                                                                | Early Failure (fall through to next IP) | Late Failure (VM exit like)                                                                                                                            |
|-------------|------------------------------------------------------------------------------------|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| System-Wide | No use of “Load IA32_RTIT_CTL” entry control or VM-entry MSR-load area             | TIP (NextIP)                            | <i>CFE.VMENTRY, FUP(CLIP) if EventEn=1</i><br><i>PIP(Guest CR3, NR=1), TraceEn 0→1 Packets (See Section 33.2.8.3), PIP(HostCR3, NR=0), TIP(HostIP)</i> |
| VMM Only    | “Load IA32_RTIT_CTL” entry control or VM-entry MSR-load area used to clear TraceEn | TIP (NextIP)                            | <i>TraceEn 0→1 Packets (See Section 33.2.8.3), TIP(HostIP)</i>                                                                                         |
| VM Only     | “Load IA32_RTIT_CTL” entry control or VM-entry MSR-load area used to set TraceEn   | None                                    | None                                                                                                                                                   |

### 33.5.2.6 VMX Abort

VMX abort conditions take the processor into a shutdown state. On a VM exit that leads to VMX abort, some packets (FUP, PIP) may be generated, but any expected TIP, TIP.PGE, or TIP.PGD may be dropped.

## 33.6 TRACING AND SMM TRANSFER MONITOR (STM)

The SMM-transfer monitor (STM) is a VMM that operates inside SMM while in VMX root operation. An STM operates in conjunction with an executive monitor. The latter operates outside SMM and in VMX root operation. Transitions from the executive monitor or its VMs to the STM are called SMM VM exits. The STM returns from SMM via a VM entry to the VM in VMX non-root operation or the executive monitor in VMX root operation.

Intel PT supports tracing in an STM similar to tracing support for VMX operation as described above in Section . As a result, on a SMM VM exit resulting from #SMI, TraceEn is neither saved nor cleared by default. Software can save the state of the trace configuration MSRs and clear TraceEn using the MSR load/save lists.

Within Event Trace, SMM VM exits generate packets indicating both an #SMI and a VM exit. Similarly, VM entries that return from SMM generate packets that indicate both an RSM and a VM entry. SMM VM exits initiated by the VMCALL instruction do not generate any CFE packet, though the subsequent VM entry returning from SMM will generate a CFE.RSM.

## 33.7 PACKET GENERATION SCENARIOS

The following tables provides examples of packet generation for various operations. The following acronyms are used in the packet examples below:

- CLIP - Current LIP
- NLIP - Next Sequential LIP
- BLIP - Branch Target LIP

Table 33-55 illustrates the packets generated by a series of example operations, assuming that PacketEn (TriggerEn && ContextEn && FilterEn && BranchEn) is set before and after the operation.

**Table 33-55. Packet Generation under Different Example Operations**

| Case | Operation                             | Details                                                         | Packets                                      |
|------|---------------------------------------|-----------------------------------------------------------------|----------------------------------------------|
| 1    | Normal non-jump operation             |                                                                 | None                                         |
| 2    | Conditional branch                    | 6th branch in internal TNT buffer                               | TNT                                          |
| 3    | Conditional branch                    | 1 <sup>st</sup> ..5 <sup>th</sup> branch in internal TNT buffer | None                                         |
| 4    | Near indirect JMP or CALL             |                                                                 | TIP(BLIP)                                    |
| 5    | Direct near JMP or CALL               |                                                                 | None                                         |
| 6    | Near RET                              | Uncompressed                                                    | TIP(BLIP)                                    |
| 7    | Near RET                              | Compressed, 6th branch in internal TNT buffer                   | TNT                                          |
| 8    | Far Branch                            | Assumes no update to CR3, CS.L, or CS.D                         | TIP(BLIP)                                    |
| 9    | Far Branch                            | Assumes update to CR3                                           | PIP(NewCR3), TIP(BLIP)                       |
| 10   | Far Branch                            | Assumes update to CR3 and CS.D/CS.L                             | PIP(NewCR3), MODE.Exec, TIP(BLIP)            |
| 11   | External Interrupt or NMI             | Assumes no update to CR3, CS.D, or CS.L                         | FUP(NLIP), TIP(BLIP)                         |
| 12   | External Interrupt or NMI             | Assumes update to CR3 and CS.D/CS.L                             | FUP(NLIP), PIP(NewCR3), MODE.Exec, TIP(BLIP) |
| 13   | Exception/Fault or Software Interrupt | Assumes no update to CR3, CS.D, or CS.L                         | FUP(CLIP), TIP(BLIP)                         |
| 14   | MOV to CR3                            |                                                                 | PIP(NewCR3, NR)                              |

**Table 33-55. Packet Generation under Different Example Operations**

| Case | Operation                                                                                                            | Details                                                                                                   | Packets                                           |
|------|----------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|---------------------------------------------------|

## 33.8 SOFTWARE CONSIDERATIONS

### 33.8.1 Tracing SMM Code

Nothing prevents an SMM handler from configuring and enabling packet generation for its own use. As described in Section 33.2.9.3, SMI will always clear TraceEn, so the SMM handler would have to set TraceEn in order to enable tracing. There are some unique aspects and guidelines involved with tracing SMM code, which follow:

1. SMM should save away the existing values of any configuration MSRs that SMM intends to modify for tracing. This will allow the non-SMM tracing context to be restored before RSM.
2. It is recommended that SMM wait until it sets CSbase to 0 before enabling packet generation, to avoid possible LIP vs RIP confusion.
3. Packet output cannot be directed to SMRR memory, even while tracing in SMM.
4. Before performing RSM, SMM should take care to restore modified configuration MSRs to the values they had immediately after #SMI. This involves first disabling packet generation by clearing TraceEn, then restoring any other configuration MSRs that were modified.
5. RSM
  - Software must ensure that TraceEn=0 at the time of RSM. Tracing RSM is not a supported usage model, and the packets generated by RSM are undefined.
  - For processors on which Intel PT and LBR use are mutually exclusive (see Section 33.3.1.2), any RSM during which TraceEn is restored to 1 will suspend any LBR or BTS logging.

### 33.8.2 Cooperative Transition of Multiple Trace Collection Agents

A third-party trace-collection tool should take into consideration the fact that it may be deployed on a processor that supports Intel PT but may run under any operating system.

In such a deployment scenario, Intel recommends that tool agents follow similar principles of cooperative transition of single-use hardware resources, similar to how performance monitoring tools handle performance monitoring hardware:

- Respect the “in-use” ownership of an agent who already configured the trace configuration MSRs, see architectural MSRs with the prefix “IA32\_RTIT\_” in Chapter 2, “Model-Specific Registers (MSRs)” in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 4, where “in-use” can be determined by reading the “enable bits” in the configuration MSRs.
- Relinquish ownership of the trace configuration MSRs by clearing the “enabled bits” of those configuration MSRs.

### 33.8.3 Tracking Time

This section describes the relationships of several clock counters whose update frequencies reside in different domains that feed into the timing packets. To track time, the decoder also needs to know the regularity or irregularity of the occurrences of various timing packets that store those clock counters.

Intel PT provides time information for three different but related domains:

- Processor timestamp counter

This counter increments at the max non-turbo or P1 frequency, and its value is returned on a RDTSC. Its frequency is fixed. The TSC packet holds the lower 7 bytes of the timestamp counter value. The TSC packet occurs occasionally and are much less frequent than the frequency of the time stamp counter. The timestamp counter will continue to increment when the processor is in deep C-States, with the exception of processors reporting CPUID.80000007H:EDX.InvariantTSC[bit 8] =0.

- Core crystal clock

The ratio of the core crystal clock to timestamp counter frequency is known as P, and can be calculated as CPUID.15H:EBX[31:0] / CPUID.15H:EAX[31:0]. The frequency of the core crystal clock is fixed and lower than that of the timestamp counter. The periodic MTC packet is generated based on software-selected multiples of the crystal clock frequency. The MTC packet is expected to occur more frequently than the TSC packet.

- Processor core clock

The processor core clock frequency can vary due to P-state and thermal conditions. The CYC packet provides elapsed time as measured in processor core clock cycles relative to the last CYC packet.

A decoder can use all or some combination of these packets to track time at different resolutions throughout the trace packets.

### 33.8.3.1 Time Domain Relationships

The three domains are related by the following formula:

```
TimeStampValue = (CoreCrystalClockValue * P) + AdjustedProcessorCycles + Software_Offset;
```

The CoreCrystalClockValue, also known as the Always Running Timer (ART) value, can provide the coarse-grained component of the TSC value. P, or the TSC/ART ratio, can be derived from CPUID leaf 15H, as described in Section 33.8.3.

The AdjustedProcessorCycles component provides the fine-grained distance from the rising edge of the last core crystal clock. Specifically, it is a cycle count in the same frequency as the timestamp counter from the last crystal clock rising edge. The value is adjusted based on the ratio of the processor core clock frequency to the Maximum Non-Turbo (or P1) frequency.

The Software\_Offsets component includes software offsets that are factored into the timestamp value, such as IA32\_TSC\_ADJUST.

### 33.8.3.2 Estimating TSC within Intel PT

For many usages, it may be useful to have an estimated timestamp value for all points in the trace. The formula provided in Section 33.8.3.1 above provides the framework for how such an estimate can be calculated from the various timing packets present in the trace.

The TSC packet provides the precise timestamp value at the time it is generated; however, TSC packets are infrequent, and estimates of the current timestamp value based purely on TSC packets are likely to be very inaccurate for this reason. In order to get more precise timing information between TSC packets, CYC packets and/or MTC packets should be enabled.

MTC packets provide incremental updates of the CoreCrystalClockValue. On processors that support CPUID leaf 15H, the frequency of the timestamp counter and the core crystal clock is fixed, thus MTC packets provide a means to update the running timestamp estimate. Between two MTC packets A and B, the number of crystal clock cycles passed is calculated from the 8-bit payloads of respective MTC packets:

$(CTC_B - CTC_A)$ , where  $CTC_i = MTC_i[15:8] \ll IA32_RTIT_CTL.MTCFreq$  and  $i = A, B$ .

The time from a TSC packet to the subsequent MTC packet can be calculated using the TMA packet that follows the TSC packet. The TMA packet provides both the crystal clock value (lower 16 bits, in the CTC field) and the AdjustedProcessorCycles value (in the FastCounter field) that can be used in the calculation of the corresponding core crystal clock value of the TSC packet.

When the next MTC after a pair of TSC/TMA is seen, the number of crystal clocks passed since the TSC packet can be calculated by subtracting the TMA.CTC value from the time indicated by the MTC<sub>Next</sub> packet by

$CTC_{Delta}[15:0] = (CTC_{Next}[15:0] - TMA.CTC[15:0])$ , where  $CTC_{Next} = MTC_{Payload} \ll IA32_RTIT_CTL.MTCFreq$ .

The TMA.FastCounter field provides the number of AdjustedProcessorCycles since the last crystal clock rising edge, from which it can be determined the percentage of the next crystal clock cycle that had passed at the time of the TSC packet.

CYC packets can provide further precision of an estimated timestamp value to many non-timing packets, by providing an indication of the time passed between other timing packets (MTCs or TSCs).

When enabled, CYC packets are sent preceding each CYC-eligible packet, and provide the number of processor core clock cycles that have passed since the last CYC packet. Thus between MTCs and TSCs, the accumulated CYC values can be used to estimate the AdjustedProcessorCycles component of the timestamp value. The accumulated CPU cycles will have to be adjusted to account for the difference in frequency between the processor core clock and the P1 frequency. The necessary adjustment can be estimated using the core:bus ratio value given in the CBR packet, by multiplying the accumulated cycle count value by  $P1/CBR_{payload}$ .

Note that stand-alone TSC packets (that is, TSC packets that are not a part of a PSB+) are typically generated only when generation of other timing packets (MTCs and CYCs) has ceased for a period of time. Example scenarios include when Intel PT is re-enabled, or on wake after a sleep state. Thus any calculated estimate of the timestamp value leading up to a TSC packet will likely result in a discrepancy, which the TSC packet serves to correct.

A greater level of precision may be achieved by calculating the CPU clock frequency, see Section 33.8.3.4 below for a method to do so using Intel PT packets.

CYCs can be used to estimate time between TSCs even without MTCs, though this will likely result in a reduction in estimated TSC precision.

### 33.8.3.3 VMX TSC Manipulation

When software executes in non-Root operation, additional offset and scaling factors may be applied to the TSC value. These are optional, but may be enabled via VMCS controls on a per-VM basis. See Chapter 26, “VMX Non-Root Operation” for details on VMX TSC offsetting and TSC scaling.

Like the value returned by RDTSC, TSC packets will include these adjustments, but other timing packets (such as MTC, CYC, and CBR) are not impacted. In order to use the algorithm above to estimate the TSC value when TSC scaling is in use, it will be necessary for software to account for the scaling factor. See Section 33.5.2.4 for details.

### 33.8.3.4 Calculating Frequency with Intel PT

Because Intel PT can provide both wall-clock time and processor clock cycle time, it can be used to measure the processor core clock frequency. Either TSC or MTC packets can be used to track the wall-clock time. By using CYC packets to count the number of processor core cycles that pass in between a pair of wall-clock time packets, the ratio between processor core clock frequency and TSC frequency can be derived. If the P1 frequency is known, it can be applied to determine the CPU frequency. See Section 33.8.3.1 above for details on the relationship between TSC, MTC, and CYC.

# CHAPTER 34

## INTRODUCTION TO INTEL® SOFTWARE GUARD EXTENSIONS

---

### 34.1 OVERVIEW

Intel® Software Guard Extensions (Intel® SGX) is a set of instructions and mechanisms for memory accesses added to Intel® Architecture processors. Intel SGX can encompass two collections of instruction extensions, referred to as SGX1 and SGX2, see Table 34-1 and Table 34-2. The SGX1 extensions allow an application to instantiate a protected container, referred to as an enclave. The enclave is a trusted area of memory, where critical aspects of the application functionality have hardware-enhanced confidentiality and integrity protections. New access controls to restrict access to software not resident in the enclave are also introduced. The SGX2 extensions allow additional flexibility in runtime management of enclave resources and thread execution within an enclave.

Chapter 35 covers main concepts, objects and data structure formats that interact within the Intel SGX architecture. Chapter 36 covers operational aspects ranging from preparing an enclave, transferring control to enclave code, and programming considerations for the enclave code and system software providing support for enclave execution. Chapter 37 describes the behavior of Asynchronous Enclave Exit (AEX) caused by events while executing enclave code. Chapter 38 covers the syntax and operational details of the instruction and associated leaf functions available in Intel SGX. Chapter 39 describes interaction of various aspects of IA32 and Intel® 64 architectures with Intel SGX. Chapter 40 covers Intel SGX support for application debug, profiling, and performance monitoring.

**Figure 34-1. An Enclave Within the Application’s Virtual Address Space**

### 34.2 ENCLAVE INTERACTION AND PROTECTION

Intel SGX allows the protected portion of an application to be distributed in the clear. Before the enclave is built, the enclave code and data are free for inspection and analysis. The protected portion is loaded into an enclave where its code and data is measured. Once the application’s protected portion of the code and data are loaded into an enclave, memory access controls are in place to restrict access by external software. An enclave can prove its identity to a remote party and provide the necessary building-blocks for secure provisioning of keys and credentials. The application can also request an enclave-specific and platform-specific key that it can use to protect keys and data that it wishes to store outside the enclave.<sup>1</sup>

1. For additional information, see white papers on Intel SGX at <https://www.intel.com/content/www/us/en/developer/tools/isa-extensions/overview.html>.

Intel SGX introduces two significant capabilities to the Intel Architecture. First is the change in enclave memory access semantics. The second is protection of the address mappings of the application.

### 34.3 ENCLAVE LIFE CYCLE

Enclave memory management is divided into two parts: address space allocation and memory commitment. Address space allocation is the specification of the range of linear addresses that the enclave may use. This range is called the ELRANGE. No actual resources are committed to this region. Memory commitment is the assignment of actual memory resources (as pages) within the allocated address space. This two-phase technique allows flexibility for enclaves to control their memory usage and to adjust dynamically without overusing memory resources when enclave needs are low. Commitment adds physical pages to the enclave. An operating system may support separate allocate and commit operations.

During enclave creation, code and data for an enclave are loaded from a clear-text source, i.e., from non-enclave memory.

Untrusted application code starts using an initialized enclave typically by using the EENTER leaf function provided by Intel SGX to transfer control to the enclave code residing in the protected Enclave Page Cache (EPC). The enclave code returns to the caller via the EEXIT leaf function. Upon enclave entry, control is transferred by hardware to software inside the enclave. The software inside the enclave switches the stack pointer to one inside the enclave. When returning back from the enclave, the software swaps back the stack pointer then executes the EEXIT leaf function.

On processors that support the SGX2 extensions, an enclave writer may add memory to an enclave using the SGX2 instruction set, after the enclave is built and running. These instructions allow adding additional memory resources to the enclave for use in such areas as the heap. In addition, SGX2 instructions allow the enclave to add new threads to the enclave. The SGX2 features provide additional capabilities to the software model without changing the security properties of the Intel SGX architecture.

Calling an external procedure from an enclave could be done using the EEXIT leaf function. Software would use EEXIT and a software convention between the trusted section and the untrusted section.

An active enclave consumes resources from the Enclave Page Cache (EPC, see Section 34.5). Intel SGX provides the EREMOVE instruction that an EPC manager can use to reclaim EPC pages committed to an enclave. The EPC manager uses EREMOVE on every enclave page when the enclave is torn down. After successful execution of EREMOVE the EPC page is available for allocation to another enclave.

### 34.4 DATA STRUCTURES AND ENCLAVE OPERATION

There are 2 main data structures associated with operating an enclave, the SGX Enclave Control Structure (SECS, see Section 35.7) and the Thread Control Structure (TCS, see Section 35.8).

There is one SECS for each enclave. The SECS contains meta-data about the enclave which is used by the hardware and cannot be directly accessed by software. Included in the SECS is a field that stores the enclave build measurement value. This field, MRENCLAVE, is initialized by the ECREATE instruction and updated by every EADD and EEXTEND. It is locked by EINIT.

Every enclave contains one or more TCS structures. The TCS contains meta-data used by the hardware to save and restore thread specific information when entering/exiting the enclave. There is one field, FLAGS, that may be accessed by software. This field can only be accessed by debug enclaves. The flag bit, DBGOPTIN, allows to single step into the thread associated with the TCS. (see Section 35.8.1)

The SECS is created when ECREATE (see Table 34-1) is executed. The TCS can be created using the EADD instruction or the SGX2 instructions (see Table 34-2).

### 34.5 ENCLAVE PAGE CACHE

The Enclave Page Cache (EPC) is the secure storage used to store enclave pages when they are a part of an executing enclave. For an EPC page, hardware performs additional access control checks to restrict access to the page. After the current page access checks and translations are performed, the hardware checks that the EPC page

is accessible to the program currently executing. Generally an EPC page is only accessed by the owner of the executing enclave or an instruction which is setting up an EPC page.

The EPC is divided into EPC pages. An EPC page is 4KB in size and always aligned on a 4KB boundary.

Pages in the EPC can either be valid or invalid. Every valid page in the EPC belongs to one enclave instance. Each enclave instance has an EPC page that holds its SECS. The security metadata for each EPC page is held in an internal micro-architectural structure called Enclave Page Cache Map (EPCM, see Section 34.5.1).

The EPC is managed by privileged software. Intel SGX provides a set of instructions for adding and removing content to and from the EPC. The EPC may be configured by BIOS at boot time. On implementations in which EPC memory is part of system DRAM, the contents of the EPC are protected by an encryption engine.

### 34.5.1 Enclave Page Cache Map (EPCM)

The EPCM is a secure structure used by the processor to track the contents of the EPC. The EPCM holds one entry for each page in the EPC. The format of the EPCM is micro-architectural, and consequently is implementation dependent. However, the EPCM contains the following architectural information:

- The status of EPC page with respect to validity and accessibility.
- An SECS identifier (see Section 35.20) of the enclave to which the page belongs.
- The type of page: regular, SECS, TCS or VA.
- The linear address through which the enclave is allowed to access the page.
- The specified read/write/execute permissions on that page.

The EPCM structure is used by the CPU in the address-translation flow to enforce access-control on the EPC pages. The EPCM structure is described in Table 35-29, and the conceptual access-control flow is described in Section 35.5.

The EPCM entries are managed by the processor as part of various instruction flows.

## 34.6 ENCLAVE INSTRUCTIONS AND INTEL® SGX

The enclave instructions available with Intel SGX are organized as leaf functions under three instruction mnemonics: ENCLS (ring 0), ENCLU (ring 3), and ENCLV (VT root mode). Each leaf function uses EAX to specify the leaf function index, and may require additional implicit input registers as parameters. The use of EAX is implied implicitly by the ENCLS, ENCLU, and ENCLV instructions; ModR/M byte encoding is not used with ENCLS, ENCLU, and ENCLV. The use of additional registers does not use ModR/M encoding and is implied implicitly by the respective leaf function index.

Each leaf function index is also associated with a unique, leaf-specific mnemonic. A long-form expression of Intel SGX instruction takes the form of ENCLx[LEAF\_MNEMONIC], where 'x' is either 'S', 'U', or 'V'. The long-form expression provides clear association of the privilege-level requirement of a given "leaf mnemonic". For simplicity, the unique "Leaf\_Mnemonic" name is used (omitting the ENCLx for convenience) throughout in this document.

Details of individual SGX leaf functions are described in Chapter 38. Table 34-1 provides a summary of the instruction leaves that are available in the initial implementation of Intel SGX, which is introduced in the 6th generation Intel Core processors. Table 34-2 summarizes enhancement of Intel SGX for future Intel processors.

**Table 34-1. Supervisor and User Mode Enclave Instruction Leaf Functions in Long-Form of SGX1**

| Supervisor Instruction | Description                                 | User Instruction | Description                    |
|------------------------|---------------------------------------------|------------------|--------------------------------|
| ENCLS[EADD]            | Add an EPC page to an enclave.              | ENCLU[EENTER]    | Enter an enclave.              |
| ENCLS[EBLOCK]          | Block an EPC page.                          | ENCLU[EEXIT]     | Exit an enclave.               |
| ENCLS[ECREATE]         | Create an enclave.                          | ENCLU[EGETKEY]   | Create a cryptographic key.    |
| ENCLS[EDBGRD]          | Read data from a debug enclave by debugger. | ENCLU[EREPORT]   | Create a cryptographic report. |

**Table 34-1. Supervisor and User Mode Enclave Instruction Leaf Functions in Long-Form of SGX1**

| Supervisor Instruction | Description                                  | User Instruction | Description          |
|------------------------|----------------------------------------------|------------------|----------------------|
| ENCLS[EDBGWR]          | Write data into a debug enclave by debugger. | ENCLU[ERESUME]   | Re-enter an enclave. |
| ENCLS[EEXTEND]         | Extend EPC page measurement.                 |                  |                      |
| ENCLS[EINIT]           | Initialize an enclave.                       |                  |                      |
| ENCLS[ELDB]            | Load an EPC page in blocked state.           |                  |                      |
| ENCLS[ELDU]            | Load an EPC page in unblocked state.         |                  |                      |
| ENCLS[EPA]             | Add an EPC page to create a version array.   |                  |                      |
| ENCLS[EREMOVE]         | Remove an EPC page from an enclave.          |                  |                      |
| ENCLS[ETRACK]          | Activate EBLOCK checks.                      |                  |                      |
| ENCLS[EWB]             | Write back/invalidate an EPC page.           |                  |                      |

**Table 34-2. Supervisor and User Mode Enclave Instruction Leaf Functions in Long-Form of SGX2**

| Supervisor Instruction | Description                               | User Instruction   | Description                                                                      |
|------------------------|-------------------------------------------|--------------------|----------------------------------------------------------------------------------|
| ENCLS[EAUG]            | Allocate EPC page to an existing enclave. | ENCLU[EACCEPT]     | Accept EPC page into the enclave.                                                |
| ENCLS[EMODPR]          | Restrict page permissions.                | ENCLU[EMODPE]      | Enhance page permissions.                                                        |
| ENCLS[EMODT]           | Modify EPC page type.                     | ENCLU[EACCEPTCOPY] | Copy contents to an augmented EPC page and accept the EPC page into the enclave. |

**Table 34-3. VMX Operation and Supervisor Mode Enclave Instruction Leaf Functions in Long-Form of OVERSUB**

| VMX Operation         | Description                             | Supervisor Instruction | Description                                     |
|-----------------------|-----------------------------------------|------------------------|-------------------------------------------------|
| ENCLV[EDECVIRTCCHILD] | Decrement the virtual child page count. | ENCLS[ERDINFO]         | Read information about EPC page.                |
| ENCLV[EINCVIRTCCHILD] | Increment the virtual child page count. | ENCLS[ETRACKC]         | Activate EBLOCK checks with conflict reporting. |
| ENCLV[ESETCONTEXT]    | Set virtualization context.             | ENCLS[ELDBC/UC]        | Load an EPC page with conflict reporting.       |

## 34.7 DISCOVERING SUPPORT FOR INTEL® SGX AND ENABLING ENCLAVE INSTRUCTIONS

Detection of support of Intel SGX and enumeration of available and enabled Intel SGX resources are queried using the CPUID instruction. The enumeration interface comprises the following:

- Processor support of Intel SGX is enumerated by a feature flag in CPUID leaf 07H: CPUID.(EAX=07H, ECX=0H):EBX.SGX[bit 2]. If CPUID.(EAX=07H, ECX=0H):EBX.SGX = 1, the processor has support for Intel SGX, and requires opt-in enabling by BIOS via IA32\_FEATURE\_CONTROL MSR.  
If CPUID.(EAX=07H, ECX=0H):EBX.SGX = 1, CPUID will report via the available sub-leaves of CPUID.(EAX=12H) on available and/or configured Intel SGX resources.
- The available and configured Intel SGX resources enumerated by the sub-leaves of CPUID.(EAX=12H) depend on the state of BIOS configuration.

### 34.7.1 Intel® SGX Opt-In Configuration

On processors that support Intel SGX, IA32\_FEATURE\_CONTROL provides the SGX\_ENABLE field (bit 18). Before system software can configure and enable Intel SGX resources, BIOS is required to set IA32\_FEATURE\_CONTROL.SGX\_ENABLE = 1 to opt-in the use of Intel SGX by system software.

The semantics of setting SGX\_ENABLE follows the rules of IA32\_FEATURE\_CONTROL.LOCK (bit 0). Software is considered to have opted into Intel SGX if and only if IA32\_FEATURE\_CONTROL.SGX\_ENABLE and IA32\_FEATURE\_CONTROL.LOCK are set to 1. The setting of IA32\_FEATURE\_CONTROL.SGX\_ENABLE (bit 18) is not reflected by CPUID.

**Table 34-4. Intel® SGX Opt-in and Enabling Behavior**

| CPUID.(07H,0H):EBX.SGX | CPUID.(12H) | FEATURE_CONTROL.LOCK | FEATURE_CONTROL.SGX_ENABLE | Enclave Instruction                                      |
|------------------------|-------------|----------------------|----------------------------|----------------------------------------------------------|
| 0                      | Invalid     | X                    | X                          | #UD                                                      |
| 1                      | Valid*      | X                    | X                          | #UD**                                                    |
| 1                      | Valid*      | 0                    | X                          | #GP                                                      |
| 1                      | Valid*      | 1                    | 0                          | #GP                                                      |
| 1                      | Valid*      | 1                    | 1                          | Available (see Table 34-5 for details of SGX1 and SGX2). |

\* Leaf 12H enumeration results are dependent on enablement.  
 \*\* See list of conditions in the #UD section of the reference pages of ENCLS and ENCLU

### 34.7.2 Intel® SGX Resource Enumeration Leaves

If CPUID.(EAX=07H, ECX=0H):EBX.SGX = 1, the processor also supports querying CPUID with EAX=12H on Intel SGX resource capability and configuration. The number of available sub-leaves in leaf 12H depends on the Opt-in and system software configuration. Information returned by CPUID.12H is thread specific; software should not assume that if Intel SGX instructions are supported on one hardware thread, they are also supported elsewhere.

A properly configured processor exposes Intel SGX functionality with CPUID.EAX=12H reporting valid information (non-zero content) in three or more sub-leaves, see Table 34-5.

- CPUID.(EAX=12H, ECX=0H) enumerates Intel SGX capability, including enclave instruction opcode support.
- CPUID.(EAX=12H, ECX=1H) enumerates Intel SGX capability of processor state configuration and enclave configuration in the SECS structure (see Table 35-3).
- CPUID.(EAX=12H, ECX > 1) enumerates available EPC resources.

**Table 34-5. CPUID Leaf 12H, Sub-Leaf 0 Enumeration of Intel® SGX Capabilities**

| CPUID.(EAX=12H,ECX=0) |      | Description Behavior                                                                                                 |
|-----------------------|------|----------------------------------------------------------------------------------------------------------------------|
| Register              | Bits |                                                                                                                      |
| EAX                   | 0    | SGX1: If 1, indicates leaf functions of SGX1 instruction listed in Table 34-1 are supported.                         |
|                       | 1    | SGX2: If 1, indicates leaf functions of SGX2 instruction listed in Table 34-2 are supported.                         |
|                       | 4:2  | Reserved (0)                                                                                                         |
|                       | 5    | OVERSUB: If 1, indicates Intel SGX supports instructions: EINCVIRTCHILD, EDECVIRTCHILD, and ESETCONTEXT.             |
|                       | 6    | OVERSUB: If 1, indicates Intel SGX supports instructions: ETRACKC, ERDINFO, ELDBC, and ELDUC.                        |
|                       | 31:7 | Reserved (0)                                                                                                         |
| EBX                   | 31:0 | MISCSELECT: Reports the bit vector of supported extended features that can be written to the MISC region of the SSA. |
| ECX                   | 31:0 | Reserved (0).                                                                                                        |

**Table 34-5. CPUID Leaf 12H, Sub-Leaf 0 Enumeration of Intel® SGX Capabilities**

| CPUID.(EAX=12H,ECX=0) |       | Description Behavior                                                                                            |
|-----------------------|-------|-----------------------------------------------------------------------------------------------------------------|
| Register              | Bits  |                                                                                                                 |
| EDX                   | 7:0   | MaxEnclaveSize_Non64: the maximum supported enclave size is $2^{(EDX[7:0])}$ bytes when not in 64-bit mode.     |
|                       | 15:8  | MaxEnclaveSize_64: the maximum supported enclave size is $2^{(EDX[15:8])}$ bytes when operating in 64-bit mode. |
|                       | 31:16 | Reserved (0).                                                                                                   |

**Table 34-6. CPUID Leaf 12H, Sub-Leaf 1 Enumeration of Intel® SGX Capabilities**

| CPUID.(EAX=12H,ECX=1) |      | Description Behavior                                                                                                                                                        |
|-----------------------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Register              | Bits |                                                                                                                                                                             |
| EAX                   | 31:0 | Report the valid bits of SECS.ATTRIBUTES[31:0] that software can set with ECREATE. SECS.ATTRIBUTES[n] can be set to 1 using ECREATE only if EAX[n] is 1, where n < 32.      |
| EBX                   | 31:0 | Report the valid bits of SECS.ATTRIBUTES[63:32] that software can set with ECREATE. SECS.ATTRIBUTES[n+32] can be set to 1 using ECREATE only if EBX[n] is 1, where n < 32.  |
| ECX                   | 31:0 | Report the valid bits of SECS.ATTRIBUTES[95:64] that software can set with ECREATE. SECS.ATTRIBUTES[n+64] can be set to 1 using ECREATE only if ECX[n] is 1, where n < 32.  |
| EDX                   | 31:0 | Report the valid bits of SECS.ATTRIBUTES[127:96] that software can set with ECREATE. SECS.ATTRIBUTES[n+96] can be set to 1 using ECREATE only if EDX[n] is 1, where n < 32. |

On processors that support Intel SGX1 and SGX2, CPUID leaf 12H sub-leaf 2 report physical memory resources available for use with Intel SGX. These physical memory sections are typically allocated by BIOS as **Processor Reserved Memory**, and available to the OS to manage as EPC.

To enumerate how many EPC sections are available to the EPC manager, software can enumerate CPUID leaf 12H with sub-leaf index starting from 2, and decode the sub-leaf-type encoding (returned in EAX[3:0]) until the sub-leaf type is invalid. All invalid sub-leaves of CPUID leaf 12H return EAX/EBX/ECX/EDX with 0.

**Table 34-7. CPUID Leaf 12H, Sub-Leaf Index 2 or Higher Enumeration of Intel® SGX Resources**

| CPUID.(EAX=12H,ECX > 1) |       | Description Behavior                                                                                                                                                                                                                                                                    |
|-------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Register                | Bits  |                                                                                                                                                                                                                                                                                         |
| EAX                     | 3:0   | 0000b: This sub-leaf is invalid; EDX:ECX:EBX:EAX return 0.<br>0001b: This sub-leaf enumerates an EPC section. EBX:EAX and EDX:ECX provide information on the Enclave Page Cache (EPC) section.<br>All other encodings are reserved.                                                     |
|                         | 11:4  | Reserved (enumerate 0).                                                                                                                                                                                                                                                                 |
|                         | 31:12 | If EAX[3:0] = 0001b, these are bits 31:12 of the physical address of the base of the EPC section.                                                                                                                                                                                       |
| EBX                     | 19:0  | If EAX[3:0] = 0001b, these are bits 51:32 of the physical address of the base of the EPC section.                                                                                                                                                                                       |
|                         | 31:20 | Reserved.                                                                                                                                                                                                                                                                               |
| ECX                     | 3: 0  | If ECX[3:0] = 0000b, then all bits of the EDX:ECX pair are enumerated as 0.<br>If ECX[3:0] = 0001b, then this section has confidentiality and integrity protection.<br>If ECX[3:0] = 0010b, then this section has confidentiality protection only.<br>All other encodings are reserved. |
|                         | 11:4  | Reserved (enumerate 0).                                                                                                                                                                                                                                                                 |
|                         | 31:12 | If EAX[3:0] = 0001b, these are bits 31:12 of the size of the corresponding EPC section within the Processor Reserved Memory.                                                                                                                                                            |

## 34.8 INTEL® SGX INTERACTIONS WITH CONTROL-FLOW ENFORCEMENT TECHNOLOGY

This section discusses extensions to the Intel SGX architecture to support CET.

### 34.8.1 CET in Enclaves Model

Each enclave has its private configuration for CET that is not shared with the CET configurations of the enclosing application. On entry into the enclave, the CET state of the enclosing application is saved into scratchpad registers inside the processor and the CET state of the enclave is established. On an asynchronous exit, the enclave CET state is saved into the enclave state save area frame. On exit from the enclave, the CET state of the enclosing application is re-established from the scratchpad registers.

A new page type, PT\_SS\_FIRST, is used to denote pages in an enclave that can be used as a first page of a shadow stack.

A new page type, PT\_SS\_REST, is used to denote pages in an enclave that can be used as a non-first page of a shadow stack.

A page denoted as PT\_SS\_FIRST and PT\_SS\_REST will be a legal target for shadow\_stack\_load, shadow\_stack\_store, and regular load operations. Regular stores will be disallowed to such pages. A PT\_SS\_FIRST/PT\_SS\_REST page must be writeable in the IA page tables and in EPT.

When in enclave mode, shadow\_stack\_load and shadow\_stack\_store operations must be to addresses in the enclave ELRANGE.

The EAUG instruction is extended to allocate pages of type PT\_SS\_FIRST/PT\_SS\_REST; this page type requires specifying a SECINFO structure with page parameters. Shadow page permission must be R/W. Regular R/W pages may continue to be allocated by providing a SECINFO pointer value of 0. Regular R/W pages may also be allocated by providing a SECINFO structure that specifies the page parameters. The EAUG instruction creates a shadow-stack-restore token at offset 0xFF8 on a PT\_SS\_FIRST page. This allows a dynamically created shadow stack to be restored using the RSTORSSP instruction. The EADD and EAUG instructions disallow creation of a PT\_SS\_FIRST or PT\_SS\_REST page as the first or last page in ELRANGE.

The EADD instruction requires that the PT\_SS\_REST page be all zeroes. The EADD instruction requires that a PT\_SS\_FIRST page be all zeroes except the 8 bytes at offset 0xFF8 on that page that must have a shadow-stack-restore token. This shadow-stack-restore token must have a linear address which is the linear address of the PT\_SS\_FIRST page + 4096. As an enclave could be loaded at varying linear addresses, the enclave builder should not extend the measurement of the PT\_SS\_FIRST pages into the measurement registers. On first entry on to the enclave using a TCS, the enclave software can use the RSTORSSP instruction to restore its SSP. Subsequent to performing a RSTORSSP, the enclave software can use the INCSSP instruction to pop the previous-ssp token that is created by the RSTORSSP instruction at the top of the restored shadow stack.

On an enclave entry, the SSP will be initialized to the value in a new TCS field called PREVSSP. The PREVSSP field is written with the value of SSP on enclave exit and is loaded into SSP at enclave entry. When a TCS page is added using EADD or accepted using EACCEPT, the processor requires the PREVSSP field to be initialized to 0.

### 34.8.2 Operations Not Supported on Shadow Stack Pages

The following operations are not allowed on pages of type PT\_SS\_FIRST and PT\_SS\_REST:

- EACCEPTCOPY
- EMODPR
- EMODPE

### 34.8.3 Indirect Branch Tracking - Legacy Compatibility Treatment

The legacy code page bitmap is tested using the page offset within the ELRANGE instead of the absolute linear address of the address where ENDBRANCH was missed; see the detailed algorithm in Section 17.3.6, “Legacy Compatibility Treatment,” in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1 for additional details.

## CHAPTER 35

# ENCLAVE ACCESS CONTROL AND DATA STRUCTURES

---

### 35.1 OVERVIEW OF ENCLAVE EXECUTION ENVIRONMENT

When an enclave is created, it has a range of linear addresses to which the processor applies enhanced access control. This range is called the ELRANGE (see Section 34.3). When an enclave generates a memory access, the existing IA32 segmentation and paging architecture are applied. Additionally, linear addresses inside the ELRANGE must map to an EPC page otherwise when an enclave attempts to access that linear address a fault is generated.

The EPC pages need not be physically contiguous. System software allocates EPC pages to various enclaves. Enclaves must abide by OS/VMM imposed segmentation and paging policies. OS/VMM-managed page tables and extended page tables provide address translation for the enclave pages. Hardware requires that these pages are properly mapped to EPC (any failure generates an exception).

Enclave entry must happen through specific enclave instructions:

- ENCLU[EENTER], ENCLU[ERESUME].

Enclave exit must happen through specific enclave instructions or events:

- ENCLU[EEXIT], Asynchronous Enclave Exit (AEX).

Attempts to execute, read, or write to linear addresses mapped to EPC pages when not inside an enclave will result in the processor altering the access to preserve the confidentiality and integrity of the enclave. The exact behavior may be different between implementations. As an example a read of an enclave page may result in the return of all one's or return of ciphertext of the cache line. Writing to an enclave page may result in a dropped write or a machine check at a later time. The processor will provide the protections as described in Section 35.4 and Section 35.5 on such accesses.

### 35.2 TERMINOLOGY

A memory access to the ELRANGE and initiated by an instruction executed by an enclave is called a Direct Enclave Access (Direct EA).

Memory accesses initiated by certain Intel® SGX instruction leaf functions such as ECREATE, EADD, EDBG RD, EDBG WR, ELDU/ELDB, EWB, EREMOVE, EENTER, and ERESUME to EPC pages are called Indirect Enclave Accesses (Indirect EA). Table 35-1 lists additional details of the indirect EA of SGX1 and SGX2 extensions.

Direct EAs and Indirect EAs together are called Enclave Accesses (EAs).

Any memory access that is not an Enclave Access is called a non-enclave access.

### 35.3 ACCESS-CONTROL REQUIREMENTS

Enclave accesses have the following access-control attributes:

- All memory accesses must conform to segmentation and paging protection mechanisms.
- Code fetches from inside an enclave to a linear address outside that enclave result in a #GP(0) exception.
- Shadow-stack-load or shadow-stack-store from inside an enclave to a linear address outside that enclave results in a #GP(0) exception.
- Non-enclave accesses to EPC memory result in undefined behavior. EPC memory is protected as described in Section 35.4 and Section 35.5 on such accesses.
- EPC pages of page types PT\_REG, PT\_TCS, and PT\_TRIM must be mapped to ELRANGE at the linear address specified when the EPC page was allocated to the enclave using ENCLS[EADD] or ENCLS[EAUG] leaf functions. Enclave accesses through other linear address result in a #PF with the PFEC.SGX bit set.

- Direct EAs to any EPC pages must conform to the currently defined security attributes for that EPC page in the EPCM. These attributes may be defined at enclave creation time (EADD) or when the enclave sets them using SGX2 instructions. The failure of these checks results in a #PF with the PFEC.SGX bit set.
  - Target page must belong to the currently executing enclave.
  - Data may be written to an EPC page if the EPCM allow write access.
  - Data may be read from an EPC page if the EPCM allow read access.
  - Instruction fetches from an EPC page are allowed if the EPCM allows execute access.
  - Shadow-stack-load from an EPC page and shadow-stack-store to an EPC page are allowed only if the page type is PT\_SS\_FIRST or PT\_SS\_REST.
  - Data writes that are not shadow-stack-store are not allowed if the EPCM page type is PT\_SS\_FIRST or PT\_SS\_REST.
  - Target page must not have a restricted page type<sup>1</sup> (PT\_SECS, PT\_TCS, PT\_VA, or PT\_TRIM).
  - The EPC page must not be BLOCKED.
  - The EPC page must not be PENDING.
  - The EPC page must not be MODIFIED.

## 35.4 SEGMENT-BASED ACCESS CONTROL

Intel SGX architecture does not modify the segment checks performed by a logical processor. All memory accesses arising from a logical processor in protected mode (including enclave access) are subject to segmentation checks with the applicable segment register.

To ensure that outside entities do not modify the enclave's logical-to-linear address translation in an unexpected fashion, ENCLU[EENTER] and ENCLU[ERESUME] check that CS, DS, ES, and SS, if usable (i.e., not null), have segment base value of zero. A non-zero segment base value for these registers results in a #GP(0).

On enclave entry either via EENTER or ERESUME, the processor saves the contents of the external FS and GS registers, and loads these registers with values stored in the TCS at build time to enable the enclave's use of these registers for accessing the thread-local storage inside the enclave. On EEXIT and AEX, the contents at time of entry are restored. On AEX, the values of FS and GS are saved in the SSA frame. On ERESUME, FS and GS are restored from the SSA frame. The details of these operations can be found in the descriptions of EENTER, ERESUME, EEXIT, and AEX flows.

## 35.5 PAGE-BASED ACCESS CONTROL

### 35.5.1 Access-control for Accesses that Originate from Non-SGX Instructions

Intel SGX builds on the processor's paging mechanism to provide page-granular access-control for enclave pages. Enclave pages are designed to be accessible only from inside the currently executing enclave if they belong to that enclave. In addition, enclave accesses must conform to the access control requirements described in Section 35.3. or through certain Intel SGX instructions. Attempts to execute, read, or write to linear addresses mapped to EPC pages when not inside an enclave will result in the processor altering the access to preserve the confidentiality and integrity of the enclave. The exact behavior may be different between implementations.

### 35.5.2 Memory Accesses that Split Across ELRANGE

Memory data accesses are allowed to split across ELRANGE (i.e., a part of the access is inside ELRANGE and a part of the access is outside ELRANGE) while the processor is inside an enclave. If an access splits across ELRANGE, the

---

1. EPCM may allow write, read or execute access only for pages with page type PT\_REG.

processor splits the access into two sub-accesses (one inside ELRANGE and the other outside ELRANGE), and each access is evaluated. A code-fetch access that splits across ELRANGE results in a #GP due to the portion that lies outside of the ELRANGE.

### 35.5.3 Implicit vs. Explicit Accesses

Memory accesses originating from Intel SGX instruction leaf functions are categorized as either explicit accesses or implicit accesses. Table 35-1 lists the implicit and explicit memory accesses made by Intel SGX leaf functions.

#### 35.5.3.1 Explicit Accesses

Accesses to memory locations provided as explicit operands to Intel SGX instruction leaf functions, or their linked data structures are called explicit accesses.

Explicit accesses are always made using logical addresses. These accesses are subject to segmentation, paging, extended paging, and APIC-virtualization checks, and trigger any faults/exit associated with these checks when the access is made.

The interaction of explicit memory accesses with data breakpoints is leaf-function-specific, and is documented in Section 40.3.4.

#### 35.5.3.2 Implicit Accesses

Accesses to data structures whose physical addresses are cached by the processor are called implicit accesses. These addresses are not passed as operands of the instruction but are implied by use of the instruction.

These accesses do not trigger any access-control faults/exits or data breakpoints. Table 35-1 lists memory objects that Intel SGX instruction leaf functions access either by explicit access or implicit access. The addresses of explicit access objects are passed via register operands with the second through fourth column of Table 35-1 matching implicitly encoded registers RBX, RCX, RDX.

Physical addresses used in different implicit accesses are cached via different instructions and for different durations. The physical address of SECS associated with each EPC page is cached at the time the page is added to the enclave via ENCLS[EADD] or ENCLS[EAUG], or when the page is loaded to EPC via ENCLS[ELDB] or ENCLS[ELDU]. This binding is severed when the corresponding page is removed from the EPC via ENCLS[EREMOVE] or ENCLS[EWB]. Physical addresses of TCS and SSA pages are cached at the time of most-recent enclave entry. Exit from an enclave (ENCLU[EEXIT] or AEX) flushes this caching. Details of Asynchronous Enclave Exit is described in Chapter 37.

The physical addresses that are cached for use by implicit accesses are derived from logical (or linear) addresses after checks such as segmentation, paging, EPT, and APIC virtualization checks. These checks may trigger exceptions or VM exits. Note, however, that such exception or VM exits may not occur after a physical address is cached and used for an implicit access.

**Table 35-1. List of Implicit and Explicit Memory Access by Intel® SGX Enclave Instructions**

| Instr. Leaf  | Enum.   | Explicit 1                     | Explicit 2    | Explicit 3    | Implicit |
|--------------|---------|--------------------------------|---------------|---------------|----------|
| EACCEPT      | SGX2    | SECINFO                        | EPCPAGE       |               | SECS     |
| EACCEPTCOPY  | SGX2    | SECINFO                        | EPCPAGE (Src) | EPCPAGE (Dst) |          |

\*Details of Asynchronous Enclave Exit (AEX) is described in Section 37.4

## 35.6 INTEL® SGX DATA STRUCTURES OVERVIEW

Enclave operation is managed via a collection of data structures. Many of the top-level data structures contain sub-structures. The top-level data structures relate to parameters that may be used in enclave setup/maintenance, by Intel SGX instructions, or AEX event. The top-level data structures are:

- SGX Enclave Control Structure (SECS)
- Thread Control Structure (TCS)

Details of the top-level data structures and associated sub-structures are listed in Section 35.7 through Section 35.20.

## 35.7 SGX ENCLAVE CONTROL STRUCTURE (SECS)

The SECS data structure requires 4K-Bytes alignment.

**Table 35-2. Layout of SGX Enclave Control Structure (SECS)**

| Field                 | OFFSET (Bytes) | Size (Bytes) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| RESERVED              | 262            | 3834         | <p>The RESERVED field consists of the following:</p> <ul style="list-style-type: none"> <li>▪ EID: An 8 byte Enclave Identifier. Its location is implementation specific.</li> <li>▪ PAD: A 352 bytes padding pattern from the Signature (used for key derivation strings). It's location is implementation specific.</li> <li>▪ VIRTCHILDCNT: An 8 byte Count of virtual children that have been paged out by a VMM. Its location is implementation specific.</li> <li>▪ ENCLAVECONTEXT: An 8 byte Enclave context pointer. Its location is implementation specific.</li> <li>▪ ISVFAMILYID: A 16 byte value assigned to identify the family of products the enclave belongs to.</li> <li>▪ ISVEXTPRODID: A 16 byte value assigned to identify the product identity of the enclave.</li> <li>▪ The remaining 3226 bytes are reserved area.</li> </ul> <p>The entire 3834 byte field must be cleared prior to executing ECREATE.</p> |

### 35.7.1 ATTRIBUTES

The ATTRIBUTES data structure is comprised of bit-granular fields that are used in the SECS, the REPORT and the KEYREQUEST structures. CPUID.(EAX=12H, ECX=1) enumerates a bitmap of permitted 1-setting of bits in ATTRIBUTES.

**Table 35-3. Layout of ATTRIBUTES Structure**

| Field          | Bit Position | Description                                                                                                                                                                                                                                            |
|----------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INIT           | 0            | This bit indicates if the enclave has been initialized by EINIT. It must be cleared when loaded as part of ECREATE. For EREPORT instruction, TARGET_INFO.ATTRIBUTES[ENIT] must always be 1 to match the state after EINIT has initialized the enclave. |
| DEBUG          | 1            | If 1, the enclave permit debugger to read and write enclave data using EDBG RD and EDBG WR.                                                                                                                                                            |
| MODE64BIT      | 2            | Enclave runs in 64-bit mode.                                                                                                                                                                                                                           |
| RESERVED       | 3            | Must be Zero.                                                                                                                                                                                                                                          |
| PROVISIONKEY   | 4            | Provisioning Key is available from EGETKEY.                                                                                                                                                                                                            |
| EINITTOKEN_KEY | 5            | EINIT token key is available from EGETKEY.                                                                                                                                                                                                             |
| CET            | 6            | Enable CET attributes. When CPUID.(EAX=12H, ECX=1):EAX[6] is 0 this bit is reserved and must be 0.                                                                                                                                                     |
| KSS            | 7            | Key Separation and Sharing Enabled.                                                                                                                                                                                                                    |
| RESERVED       | 9:8          | Must be zero.                                                                                                                                                                                                                                          |
| AEXNOTIFY      | 10           | The bit indicates that threads within the enclave may receive AEX notifications.                                                                                                                                                                       |
| RESERVED       | 63:11        | Must be zero.                                                                                                                                                                                                                                          |
| XFRM           | 127:64       | XSAVE Feature Request Mask. See Section 39.7.                                                                                                                                                                                                          |

### 35.7.2 SECS.MISCSELECT Field

CPUID.(EAX=12H, ECX=0):EBX[31:0] enumerates which extended information that the processor can save into the MISC region of SSA when an AEX occurs. An enclave writer can specify via SIGSTRUCT how to set the SECS.MISCSELECT field. The bit vector of MISCSELECT selects which extended information is to be saved in the MISC region of the SSA frame when an AEX is generated. The bit vector definition of extended information is listed in Table 35-4.

If CPUID.(EAX=12H, ECX=0):EBX[31:0] = 0, SECS.MISCSELECT field must be all zeros.

The SECS.MISCSELECT field determines the size of MISC region of the SSA frame, see Section 35.9.2.

**Table 35-4. Bit Vector Layout of MISCSELECT Field of Extended Information**

| Field    | Bit Position | Description                                                                                                                                           |
|----------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| EXINFO   | 0            | Report information about page fault and general protection exception that occurred inside an enclave.                                                 |
| CPINFO   | 1            | Report information about control protection exception that occurred inside an enclave. When CPUID.(EAX=12H, ECX=0):EBX[1] is 0, this bit is reserved. |
| Reserved | 31:2         | Reserved (0).                                                                                                                                         |

### 35.7.3 SECS.CET\_ATTRIBUTES Field

The SECS.CET\_ATTRIBUTES field can be used by the enclave writer to enable various CET attributes in an enclave. This field exists when CPUID.(EAX=12,ECX=1):EAX[6] is enumerated as 1. Bits 1:0 are defined when CPUID.(EAX=7, ECX=0):ECX.CET\_SS is 1, and bits 5:2 are defined when CPUID.(EAX=7, ECX=0):EDX.CET\_IBT is 1.

**Table 35-5. Bit Vector Layout of CET\_ATTRIBUTES Field of Extended Information**

| Field        | Bit Position | Description                                                                                  |
|--------------|--------------|----------------------------------------------------------------------------------------------|
| SH_STK_EN    | 0            | When set to 1, enable shadow stacks.                                                         |
| WR_SHSTK_EN  | 1            | When set to 1, enables the WRSS{D,Q}W instructions.                                          |
| ENDBR_EN     | 2            | When set to 1, enables indirect branch tracking.                                             |
| LEG_IW_EN    | 3            | Enable legacy compatibility treatment for indirect branch tracking.                          |
| NO_TRACK_EN  | 4            | When set to 1, enables use of no-track prefix for indirect branch tracking.                  |
| SUPPRESS_DIS | 5            | When set to 1, disables suppression of CET indirect branch tracking on legacy compatibility. |
| Reserved     | 7:6          | Reserved (0).                                                                                |

## 35.8 THREAD CONTROL STRUCTURE (TCS)

Each executing thread in the enclave is associated with a Thread Control Structure. It requires 4K-Bytes alignment.

**Table 35-6. Layout of Thread Control Structure (TCS)**

| Field    | OFFSET (Bytes) | Size (Bytes) | Description                                                                                                                                                                                                                                      |
|----------|----------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STAGE    | 0              | 8            | Enclave execution state of the thread controlled by this TCS. A value of 0 indicates that this TCS is available for enclave entry. A value of 1 indicates that a logical processor is currently executing an enclave in the context of this TCS. |
| FLAGS    | 8              | 8            | The thread's execution flags (see Section 35.8.1).                                                                                                                                                                                               |
| OSSA     | 16             | 8            | Offset of the base of the State Save Area stack, relative to the enclave base. Must be page aligned.                                                                                                                                             |
| CSSA     | 24             | 4            | Current slot index of an SSA frame, cleared by EADD and EACCEPT.                                                                                                                                                                                 |
| NSSA     | 28             | 4            | Number of available slots for SSA frames.                                                                                                                                                                                                        |
| OENTRY   | 32             | 8            | Offset in enclave to which control is transferred on EENTER relative to the base of the enclave.                                                                                                                                                 |
| AEP      | 40             | 8            | The value of the Asynchronous Exit Pointer that was saved at EENTER time.                                                                                                                                                                        |
| OFSBASE  | 48             | 8            | Offset to add to the base address of the enclave for producing the base address of FS segment inside the enclave. Must be page aligned.                                                                                                          |
| OGSBASE  | 56             | 8            | Offset to add to the base address of the enclave for producing the base address of GS segment inside the enclave. Must be page aligned.                                                                                                          |
| FSLIMIT  | 64             | 4            | Size to become the new FS limit in 32-bit mode.                                                                                                                                                                                                  |
| GSLIMIT  | 68             | 4            | Size to become the new GS limit in 32-bit mode.                                                                                                                                                                                                  |
| OCETSSA  | 72             | 8            | When CPUID.(EAX=12H, ECX=1):EAX[6] is 1, this field provides the offset of the CET state save area from enclave base. When CPUID.(EAX=12H, ECX=1):EAX[6] is 0, this field is reserved and must be 0.                                             |
| PREVSSP  | 80             | 8            | When CPUID.(EAX=07H, ECX=00h):ECX[CET_SS] is 1, this field records the SSP at the time of AEX or EEXIT; used to setup SSP on entry. When CPUID.(EAX=07H, ECX=00h):ECX[CET_SS] is 0, this field is reserved and must be 0.                        |
| RESERVED | 72             | 4024         | Must be zero.                                                                                                                                                                                                                                    |

### 35.8.1 TCS.FLAGS

**Table 35-7. Layout of TCS.FLAGS Field**

| Field     | Bit Position | Description                                                                                                                                                                                                                                            |
|-----------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DBGOPTIN  | 0            | If set, allows debugging features (single-stepping, breakpoints, etc.) to be enabled and active while executing in the enclave on this TCS. Hardware clears this bit on EADD. A debugger may later modify it if the enclave's ATTRIBUTES.DEBUG is set. |
| AEXNOTIFY | 1            | A thread that enters the enclave cannot receive AEX notifications unless this flag is set to 1.                                                                                                                                                        |
| RESERVED  | 63:2         | Must be zero.                                                                                                                                                                                                                                          |

### 35.8.2 State Save Area Offset (OSSA)

The OSSA points to a stack of State Save Area (SSA) frames (see Section 35.9) used to save the processor state when an interrupt or exception occurs while executing in the enclave.

### 35.8.3 Current State Save Area Frame (CSSA)

CSSA is the index of the current SSA frame that will be used by the processor to determine where to save the processor state on an interrupt or exception that occurs while executing in the enclave. It is an index into the array of frames addressed by OSSA. CSSA is incremented on an AEX and decremented on an ERESUME.

### 35.8.4 Number of State Save Area Frames (NSSA)

NSSA specifies the number of SSA frames available for this TCS. There must be at least one available SSA frame when EENTER-ing the enclave or the EENTER will fail.

## 35.9 STATE SAVE AREA (SSA) FRAME

When an AEX occurs while running in an enclave, the architectural state is saved in the thread's current SSA frame, which is pointed to by TCS.CSSA. An SSA frame must be page aligned, and contains the following regions:

- The XSAVE region starts at the base of the SSA frame, this region contains extended feature register state in an XSAVE/FXSAVE-compatible non-compacted format.
- A Pad region: software may choose to maintain a pad region separating the XSAVE region and the MISC region. Software choose the size of the pad region according to the sizes of the MISC and GPRSGX regions.
- The GPRSGX region. The GPRSGX region is the last region of an SSA frame (see Table 35-8). This is used to hold the processor general purpose registers (RAX ... R15), the RIP, the outside RSP and RBP, RFLAGS, and the AEX information.
- The MISC region (If CPUIDEAX=12H, ECX=0):EBX[31:0] != 0). The MISC region is adjacent to the GRPSGX region, and may contain zero or more components of extended information that would be saved when an AEX occurs. If the MISC region is absent, the region between the GPRSGX and XSAVE regions is the pad region that software can use. If the MISC region is present, the region between the MISC and XSAVE regions is the pad region that software can use. See additional details in Section 35.9.2.

**Table 35-8. Top-to-Bottom Layout of an SSA Frame**

| Region | Offset (Byte)                 | Size (Bytes)                                      | Description                                                                                                                                                                                                                                                                                              |
|--------|-------------------------------|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| XSAVE  | 0                             | Calculate using CPUID leaf 0DH information        | The size of XSAVE region in SSA is derived from the enclave's support of the collection of processor extended states that would be managed by XSAVE. The enablement of those processor extended state components in conjunction with CPUID leaf 0DH information determines the XSAVE region size in SSA. |
| Pad    | End of XSAVE region           | Chosen by enclave writer                          | Ensure the end of GPRSGX region is aligned to the end of a 4KB page.                                                                                                                                                                                                                                     |
| MISC   | base of GPRSGX - sizeof(MISC) | Calculate from highest set bit of SECS.MISCSELECT | See Section 35.9.2.                                                                                                                                                                                                                                                                                      |
| GPRSGX | SSAFRAMESIZE - 176            | 176                                               | See Table 35-9 for layout of the GPRSGX region.                                                                                                                                                                                                                                                          |

### 35.9.1 GPRSGX Region

The layout of the GPRSGX region is shown in Table 35-9.

**Table 35-9. Layout of GPRSGX Portion of the State Save Area**

| Field    | OFFSET (Bytes) | Size (Bytes) | Description                                                                                                              |
|----------|----------------|--------------|--------------------------------------------------------------------------------------------------------------------------|
| RAX      | 0              | 8            |                                                                                                                          |
| RCX      | 8              | 8            |                                                                                                                          |
| RDX      | 16             | 8            |                                                                                                                          |
| RBX      | 24             | 8            |                                                                                                                          |
| RSP      | 32             | 8            |                                                                                                                          |
| RBP      | 40             | 8            |                                                                                                                          |
| RSI      | 48             | 8            |                                                                                                                          |
| RDI      | 56             | 8            |                                                                                                                          |

### 35.9.1.1 EXITINFO

EXITINFO contains the information used to report exit reasons to software inside the enclave. It is a 4 byte field laid out as in Table 35-10. The VALID bit is set only for the exceptions conditions which are reported inside an enclave. See Table 35-11 for which exceptions are reported inside the enclave. If the exception condition is not one reported inside the enclave then VECTOR and EXIT\_TYPE are cleared.

When a higher priority event, such as SMI, and a pending debug exception occur at the same time when executing inside an enclave, the higher priority event has precedence. As an example for an SMI, the SSA exit info is zero. The debug exception will be delivered upon return from the SMI. In such cases, the EXITINFO field will not contain the information of a debug exception.

**Table 35-10. Layout of EXITINFO Field**

| Field     | Bit Position | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VECTOR    | 7:0          | Exception number of exceptions reported inside enclave.                                                                                                                                                                                                                                                                                                                                          |

| RESERVED  | 30:11        | Reserved as zero.                                                                                                                                                                                                                                                                                                                                                                                |
| VALID     | 31           | 0: unsupported exceptions.<br>1: Supported exceptions. Includes two categories: <ul style="list-style-type: none"><li>• Unconditionally supported exceptions: #DE, #DB, #BP, #BR, #UD, #MF, #AC, #XM.</li><li>• Conditionally supported exception:<ul style="list-style-type: none"><li>– #PF, #GP if SECS.MISCSELECT.EXINFO = 1.</li><li>– #CP if SECS.MISCSELECT.CPINFO=1.</li></ul></li></ul> |

### 35.9.1.2 VECTOR Field Definition

Table 35-11 contains the VECTOR field. This field contains information about some exceptions which occur inside the enclave. These vector values are the same as the values that would be used when vectoring into regular exception handlers. All values not shown are not reported inside an enclave.

**Table 35-11. Exception Vectors**

| Name | Vector # | Description                                                                |
|------|----------|----------------------------------------------------------------------------|
| #DE  | 0        | Divider exception.                                                         |
| #DB  | 1        | Debug exception.                                                           |
| #BP  | 3        | Breakpoint exception.                                                      |
| #BR  | 5        | Bound range exceeded exception.                                            |
| #UD  | 6        | Invalid opcode exception.                                                  |
| #GP  | 13       | General protection exception. Only reported if SECS.MISCSELECT.EXINFO = 1. |
| #PF  | 14       | Page fault exception. Only reported if SECS.MISCSELECT.EXINFO = 1.         |

**Table 35-11. Exception Vectors (Contd.)**

| Name | Vector # | Description                                                              |
|------|----------|--------------------------------------------------------------------------|
| #MF  | 16       | x87 FPU floating-point error.                                            |
| #AC  | 17       | Alignment check exceptions.                                              |
| #XM  | 19       | SIMD floating-point exceptions.                                          |
| #CP  | 21       | Control protection exception. Only reported if SECS.MISCSELECT.CPINFO=1. |

## 35.9.2 MISC Region

The layout of the MISC region is shown in Table 35-12. The number of components that the processor supports in the MISC region corresponds to the bits of CPUID.(EAX=12H, ECX=0):EBX[31:0] set to 1. Each set bit in CPUID.(EAX=12H, ECX=0):EBX[31:0] has a defined size for the corresponding component, as shown in Table 35-12. Enclave writers needs to do the following:

- Decide which MISC region components will be supported for the enclave.
- Allocate an SSA frame large enough to hold the components chosen above.
- Instruct each enclave builder software to set the appropriate bits in SECS.MISCSELECT.

The first component, EXINFO, starts next to the GPRSGX region. Additional components in the MISC region grow in ascending order within the MISC region towards the XSAVE region.

The size of the MISC region is calculated as follows:

- If CPUID.(EAX=12H, ECX=0):EBX[31:0] = 0, MISC region is not supported.
- If CPUID.(EAX=12H, ECX=0):EBX[31:0] != 0, the size of MISC region is derived from sum of the highest bit set in SECS.MISCSELECT and the size of the MISC component corresponding to that bit. Offset and size information of currently defined MISC components are listed in Table 35-12. For example, if the highest bit set in SECS.MISCSELECT is bit 0, the MISC region offset is OFFSET(GPRSGX)-16 and size is 16 bytes.
- The processor saves a MISC component i in the MISC region if and only if SECS.MISCSELECT[i] is 1.

**Table 35-12. Layout of MISC region of the State Save Area**

| MISC Components  | OFFSET (Bytes)     | Size (Bytes) | Description                                                                                                                                                                                                                                                                                                                                                                   |
|------------------|--------------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EXINFO           | Offset(GPRSGX) -16 | 16           | If CPUID.(EAX=12H, ECX=0):EBX[0] = 1, exception information on #GP or #PF that occurred inside an enclave can be written to the EXINFO structure if specified by SECS.MISCSELECT[0] = 1.<br>If CPUID.(EAX=12H, ECX=0):EBX[1] = 1, exception information on #CP that occurred inside an enclave can be written to the EXINFO structure if specified by SECS.MISCSELECT[1] = 1. |
| Future Extension | Below EXINFO       | TBD          | Reserved. (Zero size if CPUID.(EAX=12H, ECX=0):EBX[31:1] =0).                                                                                                                                                                                                                                                                                                                 |

### 35.9.2.1 EXINFO Structure

Table 35-13 contains the layout of the EXINFO structure that provides additional information.

**Table 35-13. Layout of EXINFO Structure**

| Field    | OFFSET (Bytes) | Size (Bytes) | Description                                                                                                                                |
|----------|----------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| MADDR    | 0              | 8            | If #PF: contains the page fault linear address that caused a page fault.<br>If #GP: the field is cleared.<br>If #CP: the field is cleared. |
| ERRCD    | 8              | 4            | Exception error code for either #GP or #PF.                                                                                                |
| RESERVED | 12             | 4            |                                                                                                                                            |

### 35.9.2.2 Page Fault Error Code

Table 35-14 contains page fault error code that may be reported in EXINFO.ERRCD.

**Table 35-14. Page Fault Error Code**

| Name             | Bit Position | Description                                     |
|------------------|--------------|-------------------------------------------------|
| P                | 0            | Same as non-SGX page fault exception P flag.    |
| W/R              | 1            | Same as non-SGX page fault exception W/R flag.  |
| U/S <sup>1</sup> | 2            | Always set to 1 (user mode reference).          |
| RSVD             | 3            | Same as non-SGX page fault exception RSVD flag. |
| I/D              | 4            | Same as non-SGX page fault exception I/D flag.  |
| PK               | 5            | Protection Key induced fault.                   |
| RSVD             | 14:6         | Reserved.                                       |
| SGX              | 15           | EPCM induced fault.                             |
| RSVD             | 31:5         | Reserved.                                       |

**NOTES:**

1. Page faults incident to enclave mode that report U/S=0 are not reported in EXINFO.

## 35.10 CET STATE SAVE AREA FRAME

The CET state save area consists of an array of CET state save frames. The number of CET state save frames is equal to the TCS.NSSA. The current CET SSA frame is indicated by TCS.CSSA. The offset of the CET state save area is specified by TCS.OCETSSA.

**Table 35-15. Layout of CET State Save Area Frame**

| Field          | Offset (Bytes) | Size (Bytes) | Description                                                                                                                                                                                                                        |
|----------------|----------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SSP            | 0              | 8            | Shadow Stack Pointer.<br>This field is reserved when CPUID.(EAX=7, ECX=0):ECX[CET_SS] is 0.                                                                                                                                        |
| IB_TRACK_STATE | 8              | 8            | Indirect branch tracker state:<br>Bit 0: SUPPRESS – suppressed(1), tracking(0)<br>Bit 1: TRACKER - IDLE (0), WAIT_FOR_ENDBRANCH (1)<br>Bits 63:2 – Reserved<br>This field is reserved when CPUID.(EAX=7, ECX=0):EDX[CET_IBT] is 0. |

## 35.11 PAGE INFORMATION (PAGEINFO)

PAGEINFO is an architectural data structure that is used as a parameter to the EPC-management instructions. It requires 32-Byte alignment.

**Table 35-16. Layout of PAGEINFO Data Structure**

| Field        | OFFSET (Bytes) | Size (Bytes) | Description                                                                            |
|--------------|----------------|--------------|----------------------------------------------------------------------------------------|
| LINADDR      | 0              | 8            | Enclave linear address.                                                                |
| SRCPGE       | 8              | 8            | Effective address of the page where contents are located.                              |
| SECINFO/PCMD | 16             | 8            | Effective address of the SECINFO or PCMD (for ELDU, ELDB, EWB) structure for the page. |
| SECS         | 24             | 8            | Effective address of EPC slot that currently contains the SECS.                        |

## 35.12 SECURITY INFORMATION (SECINFO)

The SECINFO data structure holds meta-data about an enclave page.

**Table 35-17. Layout of SECINFO Data Structure**

| Field    | OFFSET (Bytes) | Size (Bytes) | Description                                     |
|----------|----------------|--------------|-------------------------------------------------|
| FLAGS    | 0              | 8            | Flags describing the state of the enclave page. |
| RESERVED | 8              | 56           | Must be zero.                                   |

### 35.12.1 SECINFO.FLAGS

The SECINFO.FLAGS are a set of fields describing the properties of an enclave page.

**Table 35-18. Layout of SECINFO.FLAGS Field**

| Field     | Bit Position | Description                                                                                                                                         |
|-----------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| R         | 0            | If 1 indicates that the page can be read from inside the enclave; otherwise the page cannot be read from inside the enclave.                        |
| W         | 1            | If 1 indicates that the page can be written from inside the enclave; otherwise the page cannot be written from inside the enclave.                  |
| X         | 2            | If 1 indicates that the page can be executed from inside the enclave; otherwise the page cannot be executed from inside the enclave.                |
| PENDING   | 3            | If 1 indicates that the page is in the PENDING state; otherwise the page is not in the PENDING state.                                               |
| MODIFIED  | 4            | If 1 indicates that the page is in the MODIFIED state; otherwise the page is not in the MODIFIED state.                                             |
| PR        | 5            | If 1 indicates that a permission restriction operation on the page is in progress, otherwise a permission restriction operation is not in progress. |
| RESERVED  | 7:6          | Must be zero.                                                                                                                                       |
| PAGE_TYPE | 15:8         | The type of page that the SECINFO is associated with.                                                                                               |
| RESERVED  | 63:16        | Must be zero.                                                                                                                                       |

### 35.12.2 PAGE\_TYPE Field Definition

The SECINFO flags and EPC flags contain bits indicating the type of page.

**Table 35-19. Supported PAGE\_TYPE**

| TYPE        | Value      | Description                                                                                                                                         |
|-------------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| PT_SECS     | 0          | Page is an SECS.                                                                                                                                    |
| PT_TCS      | 1          | Page is a TCS.                                                                                                                                      |
| PT_REG      | 2          | Page is a regular page.                                                                                                                             |
| PT_VA       | 3          | Page is a Version Array.                                                                                                                            |
| PT_TRIM     | 4          | Page is in trimmed state.                                                                                                                           |
| PT_SS_FIRST | 5          | When CPUID.(EAX=12H, ECX=1):EAX[6] is 1, Page is first page of a shadow stack. When CPUID.(EAX=12H, ECX=1):EAX[6] is 0, this value is reserved.     |
| PT_SS_REST  | 6          | When CPUID.(EAX=12H, ECX=1):EAX[6] is 1, Page is not first page of a shadow stack. When CPUID.(EAX=12H, ECX=1):EAX[6] is 0, this value is reserved. |
|             | All others | Reserved.                                                                                                                                           |

## 35.13 PAGING CRYPTO METADATA (PCMD)

The PCMD structure is used to keep track of crypto meta-data associated with a paged-out page. Combined with PAGEINFO, it provides enough information for the processor to verify, decrypt, and reload a paged-out EPC page. The size of the PCMD structure (128 bytes) is architectural.

EWB calculates the Message Authentication Code (MAC) value and writes out the PCMD. ELDB/U reads the fields and checks the MAC.

The format of PCMD is as follows:

**Table 35-20. Layout of PCMD Data Structure**

| Field     | OFFSET (Bytes) | Size (Bytes) | Description                                                                                          |
|-----------|----------------|--------------|------------------------------------------------------------------------------------------------------|
| SECINFO   | 0              | 64           | Flags describing the state of the enclave page; R/W by software.                                     |
| ENCLAVEID | 64             | 8            | Enclave Identifier used to establish a cryptographic binding between paged-out page and the enclave. |
| RESERVED  | 72             | 40           | Must be zero.                                                                                        |
| MAC       | 112            | 16           | Message Authentication Code for the page, page meta-data and reserved field.                         |

## 35.14 ENCLAVE SIGNATURE STRUCTURE (SIGSTRUCT)

SIGSTRUCT is a structure created and signed by the enclave developer that contains information about the enclave. SIGSTRUCT is processed by the EINIT leaf function to verify that the enclave was properly built.

SIGSTRUCT includes ENCLAVEHASH as SHA256 digest, as defined in FIPS PUB 180-4. The digests are byte strings of length 32. Each of the 8 HASH dwords is stored in little-endian order.

SIGSTRUCT includes four 3072-bit integers (MODULUS, SIGNATURE, Q1, Q2). Each such integer is represented as a byte strings of length 384, with the most significant byte at the position "offset + 383", and the least significant byte at position "offset".

The (3072-bit integer) SIGNATURE should be an RSA signature, where: a) the RSA modulus (MODULUS) is a 3072-bit integer; b) the public exponent is set to 3; c) the signing procedure uses the EMSA-PKCS1-v1.5 format with DER encoding of the "DigestInfo" value as specified in of PKCS#1 v2.1/RFC 3447.

The 3072-bit integers Q1 and Q2 are defined by:

q1 = floor(Signature^2 / Modulus);

q2 = floor((Signature^3 - q1 \* Signature \* Modulus) / Modulus);

SIGSTRUCT must be page aligned

In column 5 of Table 35-21, 'Y' indicates that this field should be included in the signature generated by the developer.

**Table 35-21. Layout of Enclave Signature Structure (SIGSTRUCT)**

| Field     | OFFSET (Bytes) | Size (Bytes) | Description                                                            | Signed |
|-----------|----------------|--------------|------------------------------------------------------------------------|--------|
| HEADER    | 0              | 16           | Must be byte stream<br>06000000E100000000001000000000H                 | Y      |
| VENDOR    | 16             | 4            | Intel Enclave: 00008086H<br>Non-Intel Enclave: 00000000H               | Y      |
| DATE      | 20             | 4            | Build date is yyyyymmdd in hex:<br>yyyy=4 digit year, mm=1-12, dd=1-31 | Y      |
| HEADER2   | 24             | 16           | Must be byte stream<br>0101000060000000600000001000000H                | Y      |
| SWDEFINED | 40             | 4            | Available for software use.                                            | Y      |

**Table 35-21. Layout of Enclave Signature Structure (SIGSTRUCT)**

| Field               | OFFSET (Bytes) | Size (Bytes) | Description                                                                                                                                                                              | Signed |
|---------------------|----------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| RESERVED            | 44             | 84           | Must be zero.                                                                                                                                                                            | Y      |
| MODULUS             | 128            | 384          | Module Public Key (keylength=3072 bits).                                                                                                                                                 | N      |
| EXPONENT            | 512            | 4            | RSA Exponent = 3.                                                                                                                                                                        | N      |
| SIGNATURE           | 516            | 384          | Signature over Header and Body.                                                                                                                                                          | N      |
| MISCSELECT*         | 900            | 4            | Bit vector specifying Extended SSA frame feature set to be used.                                                                                                                         | Y      |
| MISCMASK*           | 904            | 4            | Bit vector mask of MISCSELECT to enforce.                                                                                                                                                | Y      |

\* If CPUID.(EAX=12H, ECX=0):EBX[31:0] = 0, MISCSELECT must be 0.  
If CPUID.(EAX=12H, ECX=0):EBX[31:0] != 0, enclave writers must specify MISCSELECT such that each cleared bit in MISCMASK must also specify the corresponding bit as 0 in MISCSELECT.

## 35.15 EINIT TOKEN STRUCTURE (EINITTOKEN)

The EINIT token is used by EINIT to verify that the enclave is permitted to launch. EINIT token is generated by an enclave in possession of the EINITTOKEN key (the Launch Enclave).

EINIT token must be 512-Byte aligned.

**Table 35-22. Layout of EINIT Token (EINITTOKEN)**

### 35.16.1 REPORTDATA

REPORTDATA is a 64-Byte data structure that is provided by the enclave and included in the REPORT. It can be used to securely pass information from the enclave to the target enclave.

### 35.17 REPORT TARGET INFO (TARGETINFO)

This structure is an input parameter to the EREPORT leaf function. The address of TARGETINFO is specified as an effective address in RBX. It is used to identify the target enclave which will be able to cryptographically verify the REPORT structure returned by EREPORT. TARGETINFO must be 512-Byte aligned.

**Table 35-24. Layout of TARGETINFO Data Structure**

| Field          | OFFSET (Bytes) | Size (Bytes) | Description                                                                                                                                                                   |
|----------------|----------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MEASUREMENT    | 0              | 32           | The MRENCLAVE of the target enclave.                                                                                                                                          |
| ATTRIBUTES     | 32             | 16           | The ATTRIBUTES field of the target enclave.                                                                                                                                   |

### 35.18 KEY REQUEST (KEYREQUEST)

This structure is an input parameter to the EGETKEY leaf function. It is passed in as an effective address in RBX and must be 512-Byte aligned. It is used for selecting the appropriate key and any additional parameters required in the derivation of that key.

**Table 35-25. Layout of KEYREQUEST Data Structure**

| Field                   | OFFSET (Bytes) | Size (Bytes) | Description                                                                                                                                                                                                                        |

### 35.18.2 Key Request Policy Structure

**Table 35-27. Layout of KEYPOLICY Field**

| Field        | Bit Position | Description                                                          |
|--------------|--------------|----------------------------------------------------------------------|
| MRENCLAVE    | 0            | If 1, derive key using the enclave's MRENCLAVE measurement register. |
| MRSIGNER     | 1            | If 1, derive key using the enclave's MRSIGNER measurement register.  |
| NOISVPRODID  | 2            | If 1, derive key WITHOUT using the enclave' ISVPRODID value.         |
| CONFIGID     | 3            | If 1, derive key using the enclave's CONFIGID value.                 |
| ISVFAMILYID  | 4            | If 1, derive key using the enclave ISVFAMILYID value.                |
| ISVEXTPRODID | 5            | If 1, derive key using enclave's ISVEXTPRODID value.                 |
| RESERVED     | 15:6         | Must be zero.                                                        |

## 35.19 VERSION ARRAY (VA)

In order to securely store the versions of evicted EPC pages, Intel SGX defines a special EPC page type called a Version Array (VA). Each VA page contains 512 slots, each of which can contain an 8-byte version number for a page evicted from the EPC. When an EPC page is evicted, software chooses an empty slot in a VA page; this slot receives the unique version number of the page being evicted. When the EPC page is reloaded, there must be a VA slot that must hold the version of the page. If the page is successfully reloaded, the version in the VA slot is cleared.

VA pages can be evicted, just like any other EPC page. When evicting a VA page, a version slot in some other VA page must be used to hold the version for the VA being evicted. A Version Array Page must be 4K-Bytes aligned.

**Table 35-28. Layout of Version Array Data Structure**

| Field    | OFFSET (Bytes) | Size (Bytes) | Description      |
|----------|----------------|--------------|------------------|
| Slot 0   | 0              | 8            | Version Slot 0   |
| Slot 1   | 8              | 8            | Version Slot 1   |
| ...      |                |              |                  |
| Slot 511 | 4088           | 8            | Version Slot 511 |

## 35.20 ENCLAVE PAGE CACHE MAP (EPCM)

EPCM is a secure structure used by the processor to track the contents of the EPC. The EPCM holds exactly one entry for each page that is currently loaded into the EPC. EPCM is not accessible by software, and the layout of EPCM fields is implementation specific.

**Table 35-29. Content of an Enclave Page Cache Map Entry**

| Field          | Description                                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------|
| VALID          | Indicates whether the EPCM entry is valid.                                                                                         |
| R              | Read access; indicates whether enclave accesses for reads are allowed from the EPC page referenced by this entry.                  |
| W              | Write access; indicates whether enclave accesses for writes are allowed to the EPC page referenced by this entry.                  |
| X              | Execute access; indicates whether enclave accesses for instruction fetches are allowed from the EPC page referenced by this entry. |
| PT             | EPCM page type (PT_SECS, PT_TCS, PT_REG, PT_VA, PT_TRIM, PT_SS_FIRST, PT_SS_REST).                                                 |
| ENCLAVESECS    | SECS identifier of the enclave to which the EPC page belongs.                                                                      |
| ENCLAVEADDRESS | Linear enclave address of the EPC page.                                                                                            |
| BLOCKED        | Indicates whether the EPC page is in the blocked state.                                                                            |
| PENDING        | Indicates whether the EPC page is in the pending state.                                                                            |
| MODIFIED       | Indicates whether the EPC page is in the modified state.                                                                           |
| PR             | Indicates whether the EPC page is in a permission restriction state.                                                               |

## 35.21 READ INFO (RDINFO)

The RDINFO structure contains status information about an EPC page. It must be aligned to 32-Bytes.

**Table 35-30. Layout of RDINFO Structure**

| Field          | OFFSET (Bytes) | Size (Bytes) | Description                                            |
|----------------|----------------|--------------|--------------------------------------------------------|
| STATUS         | 0              | 8            | Page status information.                               |
| FLAGS          | 8              | 8            | EPCM state of the page.                                |
| ENCLAVECONTEXT | 16             | 8            | Context pointer describing the page's parent location. |

### 35.21.1 RDINFO Status Structure

**Table 35-31. Layout of RDINFO STATUS Structure**

| Field            | Bit Position | Description                                                                                                                                                        |
|------------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CHILDPRESENT     | 0            | Indicates that the page has one or more child pages present (always zero for non-SECS pages). In VMX non-root operation includes the presence of virtual children. |
| VIRTCHILDPRESENT | 1            | Indicates that the page has one or more virtual child pages present (always zero for non-SECS pages). In VMX non-root operation this value is always zero.         |
| RESERVED         | 63:2         |                                                                                                                                                                    |

### 35.21.2 RDINFO Flags Structure

**Table 35-32. Layout of RDINFO FLAGS Structure**

| Field     | Bit Position | Description                                                                                                                        |
|-----------|--------------|------------------------------------------------------------------------------------------------------------------------------------|
| R         | 0            | Read access; indicates whether enclave accesses for reads are allowed from the EPC page referenced by this entry.                  |
| W         | 1            | Write access; indicates whether enclave accesses for writes are allowed to the EPC page referenced by this entry.                  |
| X         | 2            | Execute access; indicates whether enclave accesses for instruction fetches are allowed from the EPC page referenced by this entry. |
| PENDING   | 3            | Indicates whether the EPC page is in the pending state.                                                                            |
| MODIFIED  | 4            | Indicates whether the EPC page is in the modified state.                                                                           |
| PR        | 5            | Indicates whether the EPC page is in a permission restriction state.                                                               |
| RESERVED  | 7:6          |                                                                                                                                    |
| PAGE_TYPE | 15:8         | Indicates the page type of the EPC page.                                                                                           |
| RESERVED  | 62:16        |                                                                                                                                    |
| BLOCKED   | 63           | Indicates whether the EPC page is in the blocked state.                                                                            |

# CHAPTER 36

## ENCLAVE OPERATION

The following aspects of enclave operation are described in this chapter:

- Enclave creation: Includes loading code and data from outside of enclave into the EPC and establishing the enclave entity.
- Adding pages and measuring the enclave.
- Initialization of an enclave: Finalizes the cryptographic log and establishes the enclave identity and sealing identity.
- Enclave entry and exiting including:
  - Controlled entry and exit.
  - Asynchronous Enclave Exit (AEX) and resuming execution after an AEX.

### 36.1 CONSTRUCTING AN ENCLAVE

Figure 36-1 illustrates a typical Enclave memory layout.

Figure 36-1. Enclave Memory Layout

The enclave creation, commitment of memory resources, and finalizing the enclave's identity with measurement comprises multiple phases. This process can be illustrated by the following exemplary steps:

1. The application hands over the enclave content along with additional information required by the enclave creation API to the enclave creation service running at privilege level 0.
2. The enclave creation service running at privilege level 0 uses the ECREATE leaf function to set up the initial environment, specifying base address and size of the enclave. This address range, the ELRANGE, is part of the application's address space. This reserves the memory range. The enclave will now reside in this address

region. ECREATE also allocates an Enclave Page Cache (EPC) page for the SGX Enclave Control Structure (SECS). Note that this page is not required to be a part of the enclave linear address space and is not required to be mapped into the process.

3. The enclave creation service uses the EADD leaf function to commit EPC pages to the enclave, and use EEXTEND to measure the committed memory content of the enclave. For each page to be added to the enclave:
  - Use EADD to add the new page to the enclave.
  - If the enclave developer requires measurement of the page as a proof for the content, use EEXTEND to add a measurement for 256 bytes of the page. Repeat this operation until the entire page is measured.
4. The enclave creation service uses the EINIT leaf function to complete the enclave creation process and finalize the enclave measurement to establish the enclave identity. Until an EINIT is executed, the enclave is not permitted to execute any enclave code (i.e., entering the enclave by executing EENTER would result in a fault).

### 36.1.1 ECREATE

The ECREATE leaf function sets up the initial environment for the enclave by reading an SGX Enclave Control Structure (SECS) that contains the enclave's address range (ELRANGE) as defined by BASEADDR and SIZE, the ATTRIBUTES and MISCSELECT bitmaps, and the SSAFRAMESIZE. It then securely stores this information in an Enclave Page Cache (EPC) page. ELRANGE is part of the application's address space. ECREATE also initializes a cryptographic log of the enclave's build process.

### 36.1.2 EADD and EEXTEND Interaction

Once the SECS has been created, enclave pages can be added to the enclave via EADD. This involves converting a free EPC page into either a PT\_REG or a PT\_TCS page.

When EADD is invoked, the processor will update the EPCM entry with the type of page (PT\_REG or PT\_TCS), the linear address used by the enclave to access the page, and the enclave access permissions for the page. It associates the page to the SECS provided as input. The EPCM entry information is used by hardware to manage access control to the page. EADD records EPCM information in the cryptographic log stored in the SECS and copies 4 KBytes of data from unprotected memory outside the EPC to the allocated EPC page.

System software is responsible for selecting a free EPC page. System software is also responsible for providing the type of page to be added, the attributes of the page, the contents of the page, and the SECS (enclave) to which the page is to be added as requested by the application. Incorrect data would lead to a failure of EADD or to an incorrect cryptographic log and a failure at EINIT time.

After a page has been added to an enclave, software can measure a 256 byte region as determined by the developer by invoking EEXTEND. Thus to measure an entire 4KB page, system software must execute EEXTEND 16 times. Each invocation of EEXTEND adds to the cryptographic log information about which region is being measured and the measurement of the section.

Entries in the cryptographic log define the measurement of the enclave and are critical in gaining assurance that the enclave was correctly constructed by the untrusted system software.

### 36.1.3 EINIT Interaction

Once system software has completed the process of adding and measuring pages, the enclave needs to be initialized by the EINIT leaf function. After an enclave is initialized, EADD and EEXTEND are disabled for that enclave (An attempt to execute EADD/EEXTEND to enclave after enclave initialization will result in a fault). The initialization process finalizes the cryptographic log and establishes the **enclave identity** and **sealing identity** used by EGETKEY and EREPORT.

A cryptographic hash of the log is stored as the **enclave identity**. Correct construction of the enclave results in the cryptographic hash matching the one built by the enclave owner and included as the ENCLAVEHASH field of SIGSTRUCT. The **enclave identity** provided by the EREPORT leaf function can be verified by a remote party.

The EINIT leaf function checks the EINIT token to validate that the enclave has been enabled on this platform. If the enclave is not correctly constructed, or the EINIT token is not valid for the platform, or SIGSTRUCT isn't properly signed, then EINIT will fail. See the EINIT leaf function for details on the error reporting.

The **enclave identity** is a cryptographic hash that reflects the enclave attributes and MISCSELECT value, content of the enclave, the order in which it was built, the addresses it occupies in memory, the security attributes, and access right permissions of each page. The **enclave identity** is established by the EINIT leaf function.

The **sealing identity** is managed by a sealing authority represented by the hash of the public key used to sign the SIGSTRUCT structure processed by EINIT. The sealing authority assigns a product ID (ISVPRODID) and security version number (ISVSVN) to a particular enclave identity.

EINIT establishes the sealing identity using the following steps:

1. Verifies that SIGSTRUCT is properly signed using the public key enclosed in the SIGSTRUCT.
2. Checks that the measurement of the enclave matches the measurement of the enclave specified in SIGSTRUCT.
3. Checks that the enclave's attributes and MISCSELECT values are compatible with those specified in SIGSTRUCT.
4. Finalizes the measurement of the enclave and records the **sealing identity** (the sealing authority, product id and security version number) and **enclave identity** in the SECS.
5. Sets the ATTRIBUTES.INIT bit for the enclave.

### 36.1.4 Intel® SGX Launch Control Configuration

Intel® SGX Launch Control is a set of controls that govern the creation of enclaves. Before the EINIT leaf function will successfully initialize an enclave, a designated Launch Enclave must create an EINITTOKEN for that enclave. Launch Enclaves have SECS.ATTRIBUTES.EINITTOKEN\_KEY = 1, granting them access to the EINITTOKEN\_KEY from the EGETKEY leaf function. EINITTOKEN\_KEY must be used by the Launch Enclave when computing EINITTOKEN.MAC, the Message Authentication Code of the EINITTOKEN.

The hash of the public key used to sign the SIGSTRUCT of the Launch Enclave must equal the value in the IA32\_SGXLEPUBKEYHASH MSRs. Only Launch Enclaves are allowed to launch without a valid token.

The IA32\_SGXLEPUBKEYHASH MSRs are provided to designate the platform's Launch Enclave. IA32\_SGXLEPUBKEYHASH defaults to digest of Intel's launch enclave signing key after reset.

IA32\_FEATURE\_CONTROL bit 17 controls the permissions on the IA32\_SGXLEPUBKEYHASH MSRs when CPUID.(EAX=12H, ECX=00H):EAX[0] = 1. If IA32\_FEATURE\_CONTROL is locked with bit 17 set, IA32\_SGXLEPUBKEYHASH MSRs are reconfigurable (writeable). If either IA32\_FEATURE\_CONTROL is not locked or bit 17 is clear, the MSRs are read only. By leaving these MSRs writable, system SW or a VMM can support a plurality of Launch Enclaves for hosting multiple execution environments. See Table 40.2.2 for more details.

## 36.2 ENCLAVE ENTRY AND EXITING

### 36.2.1 Controlled Entry and Exit

The EENTER leaf function is the method to enter the enclave under program control. To execute EENTER, software must supply an address of a TCS that is part of the enclave to be entered. The TCS holds the location inside the enclave to transfer control to and a pointer to the SSA frame inside the enclave that an AEX should store the register state to.

When a logical processor enters an enclave, the TCS is considered busy until the logical processor exits the enclave. An attempt to enter an enclave through a busy TCS results in a fault. Intel® SGX allows an enclave builder to define multiple TCSs, thereby providing support for multithreaded enclaves.

Software must also supply to EENTER the Asynchronous Exit Pointer (AEP) parameter. AEP is an address external to the enclave which an exception handler will return to using IRET. Typically the location would contain the ERESUME instruction. ERESUME transfers control back to the enclave, to the address retrieved from the enclave thread's saved state.

EENTER performs the following operations:

1. Check that TCS is not busy and flush all cached linear-to-physical mappings.
2. Change the mode of operation to be in enclave mode.
3. Save the old RSP, RBP for later restore on AEX (Software is responsible for setting up the new RSP, RBP to be used inside enclave).
4. Save XCR0 and replace it with the XFRM value for the enclave.
5. Check if software wishes to debug (applicable to a debuggable enclave):
  - If not debugging, then configure hardware so the enclave appears as a single instruction.
  - If debugging, then configure hardware to allow traps, breakpoints, and single steps inside the enclave.
6. Set the TCS as busy.
7. Transfer control from outside enclave to predetermined location inside the enclave specified by the TCS.

The EEXIT leaf function is the method of leaving the enclave under program control. EEXIT receives the target address outside of the enclave that the enclave wishes to transfer control to. It is the responsibility of enclave software to erase any secret from the registers prior to invoking EEXIT. To allow enclave software to easily perform an external function call and re-enter the enclave (using EEXIT and EENTER leaf functions), EEXIT returns the value of the AEP that was used when the enclave was entered.

EEXIT performs the following operations:

1. Clear enclave mode and flush all cached linear-to-physical mappings.
2. Mark TCS as not busy.
3. Transfer control from inside the enclave to a location on the outside specified as parameter to the EEXIT leaf function.

### 36.2.2 Asynchronous Enclave Exit (AEX)

Asynchronous and synchronous events, such as exceptions, interrupts, traps, SMIs, and VM exits may occur while executing inside an enclave. These events are referred to as Enclave Exiting Events (EEE). Upon an EEE, the processor state is securely saved inside the enclave (in the thread's current SSA frame) and then replaced by a synthetic state to prevent leakage of secrets. The process of securely saving state and establishing the synthetic state is called an Asynchronous Enclave Exit (AEX). Details of AEX is described in Chapter 37, "Enclave Exiting Events."

As part of most EEEs, the AEP is pushed onto the stack as the location of the eventing address. This is the location where control will return to after executing the IRET. The ERESUME leaf function can be executed from that point to reenter the enclave and resume execution from the interrupted point.

After AEX has completed, the logical processor is no longer in enclave mode and the exiting event is processed normally. Any new events that occur after the AEX has completed are treated as having occurred outside the enclave (e.g., a #PF in dispatching to an interrupt handler).

### 36.2.3 Resuming Execution After AEX

After system software has serviced the event that caused the logical processor to exit an enclave, the logical processor can continue enclave execution using ERESUME. ERESUME restores processor state and returns control to where execution was interrupted.

If the cause of the exit was an exception or a fault and was not resolved, the event will be triggered again if the enclave is re-entered using ERESUME. For example, if an enclave performs a divide by 0 operation, executing ERESUME will cause the enclave to attempt to re-execute the faulting instruction and result in another divide by 0 exception. Intel® SGX provides the means for an enclave developer to handle enclave exceptions from within the enclave. Software can enter the enclave at a different location and invoke the exception handler within the enclave by executing the EENTER leaf function. The exception handler within the enclave can read the fault information from the SSA frame and attempt to resolve the faulting condition or simply return and indicate to software that the enclave should be terminated (e.g., using EEXIT).

### 36.2.3.1 ERESUME Interaction

ERESUME restores registers depending on the mode of the enclave (32 or 64 bit).

- In 32-bit mode (IA32\_EFER.LMA = 0 || CS.L = 0), the low 32-bits of the legacy registers (EAX, EBX, ECX, EDX, ESP, EBP, ESI, EDI, EIP, and EFLAGS) are restored from the thread's GPR area of the current SSA frame. Neither the upper 32 bits of the legacy registers nor the 64-bit registers (R8 ... R15) are loaded.
- In 64-bit mode (IA32\_EFER.LMA = 1 && CS.L = 1), all 64 bits of the general processor registers (RAX, RBX, RCX, RDX, RSP, RBP, RSI, RDI, R8 ... R15, RIP, and RFLAGS) are loaded.

Extended features specified by SECS.ATTRIBUTES.XFRM are restored from the XSAVE area of the current SSA frame. The layout of the x87 area depends on the current values of IA32\_EFER.LMA and CS.L:

- IA32\_EFER.LMA = 0 || CS.L = 0
  - 32-bit load in the same format that XSAVE/FXSAVE uses with these values.
- IA32\_EFER.LMA = 1 && CS.L = 1
  - 64-bit load in the same format that XSAVE/FXSAVE uses with these values as if REX.W = 1.

### 36.2.3.2 Asynchronous Enclave Exit Notify and EDECCSSA

Asynchronous Enclave Exit Notify (AEX-Notify) is an extension to Intel SGX that allows Intel SGX enclaves to be notified after an asynchronous enclave exit (AEX) has occurred. EDECCSSA is a new Intel SGX user leaf function (ENCLU[EDECCSSA]) that can facilitate AEX notification handling, as well as software exception handling. This section provides information about changes to the Intel SGX architecture that support AEX-Notify and ENCLU[EDECCSSA].

#### NOTE

On some platforms, AEX-Notify and the EDECCSSA user leaf function may be enumerated by CPUID following a microcode update.

The following list summarizes the additions to existing Intel SGX data structures to support AEX-Notify:

- SECS.ATTRIBUTES.AEXNOTIFY: This enclave supports AEX-Notify.
- TCS.FLAGS.AEXNOTIFY: This enclave thread may receive AEX notifications.
- SSA.GPRSGX.AEXNOTIFY: Enclave-writable byte that allows enclave software to dynamically enable/disable AEX notifications.

An AEX notification is delivered by ENCLU[ERESUME] when the following conditions are met:

1. TCS.FLAGS.AEXNOTIFY is set.
2. TCS.CSSA (the current slot index of an SSA frame) is greater than zero.
3. TCS.SSA[TCS.CSSA-1].GPRSGX.AEXNOTIFY[0] is set.

Note that AEX increments TCS.CSSA, and ENCLU[ERESUME] decrements TCS.CSSA, except when an AEX notification is delivered. Instead of decrementing TCS.CSSA and restoring state from the SSA, ENCLU[ERESUME] delivers an AEX notification by behaving as ENCLU[EENTER]. Implications of this behavior include:

- The enclave thread is resumed at EnclaveBase + TCS.OENTRY.
- EAX contains the (non-decremented) value of TCS.CSSA.
- RCX contains the address of the IP following ENCLU[ERESUME].
- The architectural state saved by the most recent AEX is preserved in TCS.SSA[TCS.CSSA-1].

The enclave thread can return to the previous SSA context by invoking ENCLU[EDECCSSA], which decrements TCS.CSSA.

## 36.3 CALLING ENCLAVE PROCEDURES

### 36.3.1 Calling Convention

In standard call conventions subroutine parameters are generally pushed onto the stack. The called routine, being aware of its own stack layout, knows how to find parameters based on compile-time-computable offsets from the SP or BP register (depending on runtime conventions used by the compiler).

Because of the stack switch when calling an enclave, stack-located parameters cannot be found in this manner. Entering the enclave requires a modified parameter passing convention.

For example, the caller might push parameters onto the untrusted stack and then pass a pointer to those parameters in RAX to the enclave software. The exact choice of calling conventions is up to the writer of the edge routines; be those routines hand-coded or compiler generated.

### 36.3.2 Register Preservation

As with most systems, it is the responsibility of the callee to preserve all registers except that used for returning a value. This is consistent with conventional usage and tends to optimize the number of register save/restore operations that need be performed. It has the additional security result that it ensures that data is scrubbed from any registers that were used by enclave to temporarily contain secrets.

### 36.3.3 Returning to Caller

No registers are modified during EEXIT. It is the responsibility of software to remove secrets in registers before executing EEXIT.

## 36.4 INTEL® SGX KEY AND ATTESTATION

### 36.4.1 Enclave Measurement and Identification

During the enclave build process, two “measurements” are taken of each enclave and are stored in two 256-bit Measurement Registers (MR): MRENCLAVE and MRSIGNER. MRENCLAVE represents the enclave's contents and build process. MRSIGNER represents the entity that signed the enclave's SIGSTRUCT.

The values of the Measurement Registers are included in attestations to identify the enclave to remote parties. The MRs are also included in most keys, binding keys to enclaves with specific MRs.

#### 36.4.1.1 MRENCLAVE

MRENCLAVE is a unique 256 bit value that identifies the code and data that was loaded into the enclave during the initial launch. It is computed as a SHA256 hash that is initialized by the ECREATE leaf function. EADD and EEXTEND leaf functions record information about each page and the content of those pages. The EINIT leaf function finalizes the hash, which is stored in SECS.MRENCLAVE. Any tampering with the build process, contents of a page, page permissions, etc will result in a different MRENCLAVE value.

Figure 36-2 illustrates a simplified flow of changes to the MRENCLAVE register when building an enclave:

- Enclave creation with ECREATE.
- Copying a non-enclave source page into the EPC of an un-initialized enclave with EADD.
- Updating twice of the MRENCLAVE after modifying the enclave's page content, i.e., EEXTEND twice.
- Finalizing the enclave build with EINIT.

Details on specific values inserted in the hash are available in the individual instruction definitions.

**Figure 36-2. Measurement Flow of Enclave Build Process**

### 36.4.1.2 MRSIGNER

Each enclave is signed using a 3072 bit RSA key. The signature is stored in the SIGSTRUCT. In the SIGSTRUCT, the enclave's signer also assigns a product ID (ISVPRODID) and a security version (ISVSVN) to the enclave. MRSIGNER is the SHA-256 hash of the signer's public key. For platforms that support Key Separation and Sharing (CPUID.(EAX=12H, ECX=1).EAX.KSS[7]) the SIGSTRUCT can additionally specify an 16 byte extended product ID (ISVEXTPRODID), and a 16 byte family ID (ISVFAMILYID).

In attestation, MRSIGNER can be used to allow software to approve of an enclave based on the author rather than maintaining a list of MRENCLAVEs. It is used in key derivation to allow software to create a lineage of an application. By signing multiple enclaves with the same key, the enclaves will share the same keys and data. Combined with security version numbering, the author can release multiple versions of an application which can access keys for previous versions, but not future versions of that application.

### 36.4.1.3 CONFIGID

For platforms that support enhancements for key separation and sharing (CPUID.(EAX=12H, ECX=1).EAX.KSS[7]) when the enclave is created the platform can additionally provide 32-byte configuration identifier (CONFIGID). How this value is used is dependent on the enclave but it is intended to allow enclave creators to indicate what additional content may be accepted by the enclave post-initialization.

## 36.4.2 Security Version Numbers (SVN)

Intel® SGX supports a versioning system that allows the signer to identify different versions of the same software released by an author. The security version is independent of the functional version an author uses and is intended to specify security equivalence. Multiple releases with functional enhancements may all share the same SVN if they all have the same security properties or posture. Each enclave has an SVN and the underlying hardware has an SVN.

The SVNs are attested to in EREPORT and are included in the derivation of most keys, thus providing separation between data for older/newer versions.

### 36.4.2.1 Enclave Security Version

In the SIGSTRUCT, the MRSIGNER is associated with a 16-bit Product ID (ISVPRODID) and a 16 bit integer SVN (ISVSVN). Together they define a specific group of versions of a specific product. Most keys, including the Seal Key, can be bound to this pair.

To support upgrading from one release to another, EGETKEY will return keys corresponding to any value less than or equal to the software's ISVSVN.

### 36.4.2.2 Hardware Security Version

CPUSVN is a 128 bit value that reflects the microcode update version and authenticated code modules supported by the processor. Unlike ISVSVN, CPUSVN is not an integer and cannot be compared mathematically. Not all values are valid CPUSVNs.

Software must ensure that the CPUSVN provided to EGETKEY is valid. EREPORT will return the CPUSVN of the current environment. Software can execute EREPORT with TARGETINFO set to zeros to retrieve a CPUSVN from REPORTDATA. Software can access keys for a CPUSVN recorded previously, provided that each of the elements reflected in CPUSVN are the same or have been upgraded.

### 36.4.2.3 CONFIGID Security Version

The CONFIGID field can be used to contain the hash of a signing key for verifying the additional content. In this case, similar to the relationship between MRSIGNER and ISVSVN, CONFIGID needs a CONFIGID Security Version Number. CONFIGIDSVN can be specified at the same time as CONFIGID.

## 36.4.3 Keys

Intel® SGX provides software with access to keys unique to each processor and rooted in HW keys inserted into the processor during manufacturing.

Each enclave requests keys using the EGETKEY leaf function. The key is based on enclave parameters such as measurement, the enclave signing key, security attributes of the enclave, and the Hardware Security version of the processor itself. A full list of parameter options is specified in the KEYREQUEST structure, see details in Section 35.18.

By deriving keys using enclave properties, SGX guarantees that if two enclaves call EGETKEY, they will receive a unique key only accessible by the respective enclave. It also guarantees that the enclave will receive the same key on every future execution of EGETKEY. Some parameters are optional or configurable by software. For example, a Seal key can be based on the signer of the enclave, resulting in a key available to multiple enclaves signed by the same party.

The EGETKEY leaf function provides several key types. Each key is specific to the processor, CPUSVN, and the enclave that executed EGETKEY. The EGETKEY instruction definition details how each of these keys is derived, see Table 38-66. Additionally,

- **SEAL Key:** The Seal key is a general purpose key for the enclave to use to protect secrets. Typical uses of the Seal key are encrypting and calculating MAC of secrets on disk. There are 2 types of Seal Key described in Section 36.4.3.1.
- **REPORT Key:** This key is used to compute the MAC on the REPORT structure. The EREPORT leaf function is used to compute this MAC, and destination enclave uses the Report key to verify the MAC. The software usage flow is detailed in Section 36.4.3.2.
- **EINITTOKEN\_KEY:** This key is used by Launch Enclaves to compute the MAC on EINITTOKENs. These tokens are then verified in the EINIT leaf function. The key is only available to enclaves with ATTRIBUTE.EINITTOKEN\_KEY set to 1.
- **PROVISIONING Key and PROVISIONING SEAL Key:** These keys are used by attestation key provisioning software to prove to remote parties that the processor is genuine and identify the currently executing TCB. These keys are only available to enclaves with ATTRIBUTE.PROVISIONKEY set to 1.

### 36.4.3.1 Sealing Enclave Data

Enclaves can protect persistent data using Seal keys to provide encryption and/or integrity protection. EGETKEY provides two types of Seal keys specified in KEYREQUEST.KEYPOLICY field: MRENCLAVE-based key and MRSIGNER-based key.

The MRENCLAVE-based keys are available only to enclave instances sharing the same MRENCLAVE. If a new version of the enclave is released, the Seal keys will be different. Retrieving previous data requires additional software support.

The MRSIGNER-based keys are bound to the 3 tuple (MRSIGNER, ISVPRODID, ISVSVN). These keys are available to any enclave with the same MRSIGNER and ISVPRODID and an ISVSVN equal to or greater than the key in question. This is valuable for allowing new versions of the same software to retrieve keys created before an upgrade.

For platforms that support enhancements for key separation and sharing (CPUID.(EAX=12H, ECX=1).EAX.KSS[7]) four additional key policies for seal key derivation are provided. These add the ISVEXTPRODID, ISVFAMILYID, and CONFIGID/CONFIGSVN to the key derivation. Additionally, there is a policy to remove ISVPRODID from a key derivation to create a shared between different products that share the same MRSIGNER.

### 36.4.3.2 Using REPORTs for Local Attestation

Intel SGX provides a means for enclaves to securely identify one another, this is referred to as "Local Attestation". SGX provides a hardware assertion, REPORT that contains calling enclaves Attributes, Measurements and User supplied data (described in detail in Section 35.16). Figure 36-3 shows the basic flow of information.

1. The source enclave determines the identity of the target enclave to populate TARGETINFO.
2. The source enclave calls EREPORT instruction to generate a REPORT structure. The EREPORT instruction conducts the following:
  - Populates the REPORT with identify information about the calling enclave.
  - Derives the Report Key that is returned when the target enclave executes the EGETKEY. TARGETINFO provides information about the target.
  - Computes a MAC over the REPORT using derived target enclave Report Key.
3. Non-enclave software copies the REPORT from source to destination.
4. The target enclave executes the EGETKEY instruction to request its REPORT key, which is the same key used by EREPORT at the source.
5. The target enclave verifies the MAC and can then inspect the REPORT to identify the source.

Figure 36-3. SGX Local Attestation

## 36.5 EPC AND MANAGEMENT OF EPC PAGES

EPC layout is implementation specific, and is enumerated through CPUID (see Table 34-7 for EPC layout). EPC is typically configured by BIOS at system boot time.

### 36.5.1 EPC Implementation

EPC must be properly protected against attacks. One example of EPC implementation could use a Memory Encryption Engine (MEE). An MEE provides a cost-effective mechanism of creating cryptographically protected volatile storage using platform DRAM. These units provide integrity, replay, and confidentiality protection. Details are implementation specific.

### 36.5.2 OS Management of EPC Pages

The EPC is a finite resource. SGX1 (i.e., CPUID.(EAX=12H, ECX=0):EAX.SGX1 = 1 but CPUID.(EAX=12H, ECX=0):EAX.SGX2 = 0) provides the EPC manager with leaf functions to manage this resource and properly swap pages out of and into the EPC. For that, the EPC manager would need to keep track of all EPC entries, type and state, context affiliation, and SECS affiliation.

Enclave pages that are candidates for eviction should be moved to BLOCKED state using EBLOCK instruction that ensures no new cached virtual to physical address mappings can be created by attempts to reference a BLOCKED page.

Before evicting blocked pages, EPC manager should execute ETRACK leaf function on that enclave and ensure that there are no stale cached virtual to physical address mappings for the blocked pages remain on any thread on the platform.

After removing all stale translations from blocked pages, system software should use the EWB leaf function for securely evicting pages out of the EPC. EWB encrypts a page in the EPC, writes it to unprotected memory, and invalidates the copy in EPC. In addition, EWB also creates a cryptographic MAC (PCMD.MAC) of the page and stores it in unprotected memory. A page can be reloaded back to the processor only if the data and MAC match. To ensure that only the latest version of the evicted page can be loaded back, the version of the evicted page is stored securely in a Version Array (VA) in EPC.

SGX1 includes two instructions for reloading pages that have been evicted by system software: ELDU and ELDB. The difference between the two instructions is the value of the paging state at the end of the instruction. ELDU results in a page being reloaded and set to an UNBLOCKED state, while ELDB results in a page loaded to a BLOCKED state.

ELDB is intended for use by a Virtual Machine Monitor (VMM). When a VMM reloads an evicted page, it needs to restore it to the correct state of the page (BLOCKED vs. UNBLOCKED) as it existed at the time the page was evicted. Based on the state of the page at eviction, the VMM chooses either ELDB or ELDU.

#### 36.5.2.1 Enhancement to Managing EPC Pages

On processors supporting SGX2 (i.e., CPUID.(EAX=12H, ECX=0):EAX.SGX2 = 1), the EPC manager can manage EPC resources (while enclave is running) with more flexibility provided by the SGX2 leaf functions. The additional flexibility is described in Section 36.5.7 through Section 36.5.11.

### 36.5.3 Eviction of Enclave Pages

Intel SGX paging is optimized to allow the Operating System (OS) to evict multiple pages out of the EPC under a single synchronization.

The suggested flow for evicting a list of pages from the EPC is:

1. For each page to be evicted from the EPC:
  - a. Select an empty slot in a Version Array (VA) page.
    - If no empty VA page slots exist, create a new VA page using the EPA leaf function.

- b. Remove linear-address to physical-address mapping from the enclave context's mapping tables (page table and EPT tables).
  - c. Execute the EBLOCK leaf function for the target page. This sets the target page state to BLOCKED. At this point no new mappings of the page will be created. So any access which does not have the mapping cached in the TLB will generate a #PF.
2. For each enclave containing pages selected in step 1:
    - Execute an ETRACK leaf function pointing to that enclave's SECS. This initiates the tracking process that ensures that all caching of linear-address to physical-address translations for the blocked pages is cleared.
  3. For all logical processors executing in processes (OS) or guests (VMM) that contain the enclaves selected in step 1:
    - Issue an IPI (inter-processor interrupt) to those threads. This causes those logical processors to asynchronously exit any enclaves they might be in, and as a result flush cached linear-address to physical-address translations that might hold stale translations to blocked pages. There is no need for additional measures such as performing a "TLB shootdown".
  4. After enclaves exit, allow logical processors to resume normal operation, including enclave re-entry as the tracking logic keeps track of the activity.
  5. For each page to be evicted:
    - Evict the page using the EWB leaf function with parameters include the effective-address pointer to the EPC page, the VA slot, a 4K byte buffer to hold the encrypted page contents, and a 128 byte buffer to hold page metadata. The last three elements are tied together cryptographically and must be used to later reload the page.

At this point, system software has the only copy of each page data encrypted with its page metadata in main memory.

### 36.5.4 Loading an Enclave Page

To reload a previously evicted page, system software needs four elements: the VA slot used when the page was evicted, a buffer containing the encrypted page contents, a buffer containing the page metadata, and the parent SECS to associate this page with. If the VA page or the parent SECS are not already in the EPC, they must be reloaded first.

1. Execute ELDB/ELDU (depending on the desired BLOCKED state for the page), passing as parameters: the EPC page linear address, the VA slot, the encrypted page, and the page metadata.
2. Create a mapping in the enclave context's mapping tables (page tables and EPT tables) to allow the application to access that page (OS: system page table; VMM: EPT).

The ELDB/ELDU instruction marks the VA slot empty so that the page cannot be replayed at a later date.

### 36.5.5 Eviction of an SECS Page

The eviction of an SECS page is similar to the eviction of an enclave page. The only difference is that an SECS page cannot be evicted until all other pages belonging to the enclave have been evicted. Since all other pages have been evicted, there will be no threads executing inside the enclave and tracking with ETRACK isn't necessary. When reloading an enclave, the SECS page must be reloaded before all other constituent pages.

1. Ensure all pages are evicted from enclave.
2. Select an empty slot in a Version Array page.
  - If no VA page exists with an empty slot, create a new one using the EPA function leaf.
3. Evict the page using the EWB leaf function with parameters include the effective-address pointer to the EPC page, the VA slot, a 4K byte buffer to hold the encrypted page contents and a 128 byte buffer to hold page metadata. The last three elements are tied together cryptographically and must be used to later reload the page.

### 36.5.6 Eviction of a Version Array Page

VA pages do not belong to any enclave and tracking with ETRACK isn't necessary. When evicting the VA page, a slot in a different VA page must be specified in order to provide versioning of the evicted VA page.

1. Select a slot in a Version Array page other than the page being evicted.
  - If no VA page exists with an empty slot, create a new one using the EPA leaf function.
2. Evict the page using the EWB leaf function with parameters include the effective-address pointer to the EPC page, the VA slot, a 4K byte buffer to hold the encrypted page contents, and a 128 byte buffer to hold page metadata. The last three elements are tied together cryptographically and must be used to later reload the page.

### 36.5.7 Allocating a Regular Page

On processors that support SGX2, allocating a new page to an already initialized enclave is accomplished by invoking the EAUG leaf function. Typically, the enclave requests that the OS allocates a new page at a particular location within the enclave's address space. Once allocated, the page remains in a pending state until the enclave executes the corresponding EACCEPT leaf function to accept the new page into the enclave. Page allocation operations may be batched to improve efficiency.

The typical process for allocating a regular page is as follows:

1. Enclave requests additional memory from OS when the current allocation becomes insufficient.
2. The OS invokes the EAUG leaf function to add a new memory page to the enclave.
  - a. EAUG may only be called on a free EPC page.
  - b. Successful completion of the EAUG instruction places the target page in the VALID and PENDING state.
  - c. All dynamically created pages have the type PT\_REG and content of all zeros.
3. The OS maps the page in the enclave context's mapping tables.
4. The enclave issues an EACCEPT instruction, which verifies the page's attributes and clears the PENDING state. At that point the page becomes accessible for normal enclave use.

### 36.5.8 Allocating a TCS Page

On processors that support SGX2, allocating a new TCS page to an already initialized enclave is a two-step process. First the OS allocates a regular page with a call to EAUG. This page must then be accepted and initialized by the enclave to which it belongs. Once the page has been initialized with appropriate values for a TCS page, the enclave requests the OS to change the page's type to PT\_TCS. This change must also be accepted. As with allocating a regular page, TCS allocation operations may be batched.

A typical process for allocating a TCS page is as follows:

1. Enclave requests an additional page from the OS.
2. The OS invokes EAUG to add a new regular memory page to the enclave.
  - a. EAUG may only be called on a free EPC page.
  - b. Successful completion of the EAUG instruction places the target page in the VALID and PENDING state.
3. The OS maps the page in the enclave context's mapping tables.
4. The enclave issues an EACCEPT instruction, at which point the page becomes accessible for normal enclave use.
5. The enclave initializes the contents of the new page.
6. The enclave requests that the OS convert the page from type PT\_REG to PT\_TCS.
7. OS issues an EMODT instruction on the page.
  - a. The parameters to EMODT indicate that the regular page should be converted into a TCS.

- b. EMODT forces all access rights to a page to be removed because TCS pages may not be accessed by enclave code.
- 8. The enclave issues an EACCEPT instruction to confirm the requested modification.

### 36.5.9 Trimming a Page

On processors that support SGX2, Intel SGX supports the trimming of an enclave page as a special case of EMODT. Trimming allows an enclave to actively participate in the process of removing a page from the enclave (deallocation) by splitting the process into first removing it from the enclave's access and then removing it from the EPC using the EREMOVE leaf function. The page type PT\_TRIM indicates that a page has been trimmed from the enclave's address space and that the page is no longer accessible to enclave software. Modifications to a page in the PT\_TRIM state are not permitted; the page must be removed and then reallocated by the OS before the enclave may use the page again. Page deallocation operations may be batched to improve efficiency.

The typical process for trimming a page from an enclave is as follows:

1. Enclave signals OS that a particular page is no longer in use.
2. OS invokes the EMODT leaf function on the page, requesting that the page's type be changed to PT\_TRIM.
  - a. SECS and VA pages cannot be trimmed in this way, so the initial type of the page must be PT\_REG or PT\_TCS.
  - b. EMODT may only be called on valid enclave pages.
3. OS invokes the ETRACK leaf function on the enclave containing the page to track removal the TLB addresses from all the processors.
4. Issue an IPI (inter-processor interrupt) to flush the stale linear-address to physical-address translations for all logical processors executing in processes that contain the enclave.
5. Enclave issues an EACCEPT leaf function.
6. The OS may now permanently remove the page from the EPC (by issuing EREMOVE).

### 36.5.10 Restricting the EPCM Permissions of a Page

On processors that support SGX2, restricting the EPCM permissions associated with an enclave page is accomplished using the EMODPR leaf function. This operation requires the cooperation of the OS to flush stale entries to the page and to update the page-table permissions of the page to match. Permissions restriction operations may be batched.

The typical process for restricting the permissions of an enclave page is as follows:

1. Enclave requests that the OS to restrict the permissions of an EPC page.
2. OS performs permission restriction, flushing cached linear-address to physical-address translations, and page-table modifications.
  - a. Invokes the EMODPR leaf function to restrict permissions (EMODPR may only be called on VALID pages).
  - b. Invokes the ETRACK leaf function on the enclave containing the page to track removal of the TLB addresses from all the processor.
  - c. Issue an IPI (inter-processor interrupt) to flush the stale linear-address to physical-address translations for all logical processors executing in processes that contain the enclave.
  - d. Sends IPIs to trigger enclave thread exit and TLB shootdown.
  - e. OS informs the Enclave that all logical processors should now see the new restricted permissions.
3. Enclave invokes the EACCEPT leaf function.
  - a. Enclave may access the page throughout the entire process.
  - b. Successful call to EACCEPT guarantees that no stale cached linear-address to physical-address translations are present.

### 36.5.11 Extending the EPCM Permissions of a Page

On processors that support SGX2, extending the EPCM permissions associated with an enclave page is accomplished directly by the enclave using the EMODPE leaf function. After performing the EPCM permission extension, the enclave requests the OS to update the page table permissions to match the extended permission. Security wise, permission extension does not require enclave threads to leave the enclave as TLBs with stale references to the more restrictive permissions will be flushed on demand, but to allow forward progress, an OS needs to be aware that an application might signal a page fault.

The typical process for extending the permissions of an enclave page is as follows:

1. Enclave invokes EMODPE to extend the EPCM permissions associated with an EPC page (EMODPE may only be called on VALID pages).
2. Enclave requests that OS update the page tables to match the new EPCM permissions.
3. Enclave code resumes.
  - a. If cached linear-address to physical-address translations are present to the more restrictive permissions, the enclave thread will page fault. The SGX2-aware OS will see that the page tables permit the access and resume the thread, which can now successfully access the page because exiting cleared the TLB.
  - b. If cached linear-address to physical-address translations are not present, access to the page with the new permissions will succeed without an enclave exit.

### 36.5.12 VMM Oversubscription of EPC

On processors supporting oversubscription enhancements (i.e., CPUID.(EAX=12H, ECX=0):EAX[5]=1 & EAX[6] = 1) a Virtual Machine Monitor or other executive can more efficiently manage the EPC space available on the platform between virtualized entities. A typical process for using these instructions to support oversubscribing the physical EPC space on the platform is as follows:

1. VMM creates data structures for SECS tracking including a count of child pages.
2. VMM selects possible EPC victim pages.
3. VMM ages the victim pages. Some of the selected pages will be accessed by the guest. In this case the VMM will remove these pages from the victim pool and return them to the guest.
4. VMM makes remaining pages not present in EPT. It then issues IPI on each page to remove TLB mappings.
5. For every EPC victim page the VMM obtains the victim's SECS page info using RDINFO.
  - a. ENCLAVECONTEXT field in RDINFO structure will indicate the location of SECS, and the PAGE\_TYPE field will indicate the page type.
  - b. Child pages of SECS can be evicted.
  - c. SECS pages may be evicted if the child count is zero.
  - d. Some pages may be returned to active state depending on such things as page type or child count.
6. VMM increments its evicted page count for the SECS of each page (stored in the data structure created in 1).
7. If this is the first evicted page of that SECS, set Marker on SECS of the victim page (EINCVIRTCHILD). This locks the SECS in the guest. The guest cannot page out the SECS.
8. EBLOCK, ETRACK, EWB eviction sequence is executed for page.
9. After loading an SECS page back in, the VMM will set the correct ENCLAVECONTEXT for the guest using ESETCONTEXT instruction.

## 36.6 CHANGES TO INSTRUCTION BEHAVIOR INSIDE AN ENCLAVE

This section covers instructions whose behavior changes when executed in enclave mode.

### 36.6.1 Illegal Instructions

The instructions listed in Table 36-1 are ring 3 instructions which become illegal when executed inside an enclave. Executing these instructions inside an enclave will generate an exception.

The first row of Table 36-1 enumerates instructions that may cause a VM exit for VMM emulation. Since a VMM cannot emulate enclave execution, execution of any of these instructions inside an enclave results in an invalid-opcode exception (#UD) and no VM exit.

The second row of Table 36-1 enumerates I/O instructions that may cause a fault or a VM exit for emulation. Again, enclave execution cannot be emulated, so execution of any of these instructions inside an enclave results in #UD.

The third row of Table 36-1 enumerates instructions that load descriptors from the GDT or the LDT or that change privilege level. The former class is disallowed because enclave software should not depend on the contents of the descriptor tables and the latter because enclave execution must be entirely with CPL = 3. Again, execution of any of these instructions inside an enclave results in #UD.

The fourth row of Table 36-1 enumerates instructions that provide access to kernel information from user mode and can be used to aid kernel exploits from within enclave. Execution of any of these instructions inside an enclave results in #UD.

**Table 36-1. Illegal Instructions Inside an Enclave**

| Instructions                                                                                                                     | Result | Comment                                                  |
|----------------------------------------------------------------------------------------------------------------------------------|--------|----------------------------------------------------------|
| CPUID, GETSEC, RDPMC, SGDT, SIDT, SLDT, STR, VMCALL, VMFUNC                                                                      | #UD    | Might cause VM exit.                                     |
| IN, INS/INSB/INSW/INSD, OUT, OUTS/OUTSB/OUTSW/OUTSD                                                                              | #UD    | I/O fault may not safely recover. May require emulation. |
| Far call, Far jump, Far Ret, INT n/INTO, IRET, LDS/LES/LFS/LGS/LSS, MOV to DS/ES/SS/FS/GS, POP DS/ES/SS/FS/GS, SYSCALL, SYSENTER | #UD    | Access segment register could change privilege level.    |
| SMSW                                                                                                                             | #UD    | Might provide access to kernel information.              |
| ENCLU[EENTER], ENCLU[ERESUME]                                                                                                    | #GP    | Cannot enter an enclave from within an enclave.          |

RDTSC and RDTSCP are legal inside an enclave for processors that support SGX2 (subject to the value of CR4.TSD). For processors which support SGX1 but not SGX2, RDTSC and RDTSCP will cause #UD.

RDTSC and RDTSCP instructions may cause a VM exit when inside an enclave.

Software developers must take into account that the RDTSC/RDTSCP results are not immune to influences by other software, e.g., the TSC can be manipulated by software outside the enclave.

### 36.6.2 RDRAND and RDSEED Instructions

These instructions may cause a VM exit if the “RDRAND exiting” VM-execution control is 1. Unlike other instructions that can cause VM exits, these instructions are legal inside an enclave. As noted in Section 28.1 of the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3C, any VM exit originating on an instruction boundary inside an enclave sets bit 27 of the exit-reason field of the VMCS. If a VMM receives a VM exit due to an attempt to execute either of these instructions determines (by that bit) that the execution was inside an enclave, it can do either of two things. It can clear the “RDRAND exiting” VM-execution control and execute VMRESUME; this will result in the enclave executing RDRAND or RDSEED again, and this time a VM exit will not occur. Alternatively, the VMM might choose to discontinue execution of this virtual machine.

#### NOTE

It is expected that VMMs that virtualize Intel SGX will not set “RDRAND exiting” to 1.

### 36.6.3 PAUSE Instruction

The PAUSE instruction may cause a VM exit from an enclave if the “PAUSE exiting” VM-execution control is 1. Unlike other instructions that can cause VM exits, the PAUSE instruction is legal inside an enclave. If a VMM receives a VM exit due to the 1-setting of “PAUSE exiting”, it can do either of two things. It can clear the “PAUSE exiting” VM-

execution control and execute VMRESUME; this will result in the enclave executing PAUSE again, but this time a VM exit will not occur. Alternatively, the VMM might choose to discontinue execution of this virtual machine.

The PAUSE instruction may also cause a VM exit outside of an enclave if the “PAUSE-loop exiting” VM-execution control is 1, but as the “PAUSE-loop exiting” control is ignored at CPL > 0 (see Section 26.1.3), VM exit from an enclave due to the 1-setting of “PAUSE-LOOP exiting” will never occur.

**NOTE**

It is expected that VMMs that virtualize Intel SGX will not set “PAUSE exiting” to 1.

### 36.6.4 Executions of INT1 and INT3 Inside an Enclave

The INT1 and INT3 instructions are legal inside an enclave, however, their behavior inside an enclave differs from that outside an enclave. See Section 40.4.1 for details.

### 36.6.5 INVD Handling when Enclaves Are Enabled

Once processor reserved memory protections are activated (see Section 36.5), any execution of INVD will result in a #GP(0).

## CHAPTER 37

# ENCLAVE EXITING EVENTS

Certain events, such as exceptions and interrupts, incident to (but asynchronous with) enclave execution may cause control to transition outside of enclave mode. (Most of these also cause a change of privilege level.) To protect the integrity and security of the enclave, the processor will exit the enclave (and enclave mode) before invoking the handler for such an event. For that reason, such events are called **enclave-exiting events** (EEE); EEEs include external interrupts, non-maskable interrupts, system-management interrupts, exceptions, and VM exits.

The process of leaving an enclave in response to an EEE is called an **asynchronous enclave exit** (AEX). To protect the secrecy of the enclave, an AEX saves the state of certain registers within enclave memory and then loads those registers with fixed values called **synthetic state**.

### 37.1 COMPATIBLE SWITCH TO THE EXITING STACK OF AEX

AEXs load registers with a pre-determined synthetic state. These registers may be later pushed onto the appropriate stack in a form as defined by the enclave-exiting event. To allow enclave execution to resume after the invoking handler has processed the enclave exiting event, the asynchronous enclave exit loads the address of trampoline code outside of the enclave into RIP. This trampoline code eventually returns to the enclave by means of an ENCLU(ERESUME) leaf function. Prior to exiting the enclave the RSP and RBP registers are restored to their values prior to enclave entry.

The stack to be used is chosen using the same rules as for non-SGX mode:

- If there is a privilege level change, the stack will be the one associated with the new ring.
- If there is no privilege level change, the current application stack is used.
- If the IA-32e IST mechanism is used, the exit stack is chosen using that method.

Figure 37-1. Exit Stack Just After Interrupt with Stack Switch

In all cases, the choice of exit stack and the information pushed onto it is consistent with non-SGX operation. Figure 37-1 shows the Application and Exiting Stacks after an exit with a stack switch. An exit without a stack switch uses the Application Stack. The ERESUME leaf index value is placed into RAX, the TCS pointer is placed in RBX and the AEP (see below) is placed into RCX to facilitate resuming the enclave after the exit.

Upon an AEX, the AEP (Asynchronous Exit Pointer) is loaded into the RIP. The AEP points to a trampoline code sequence which includes the ERESUME instruction that is later used to reenter the enclave.

The following bits of RFLAGS are cleared before RFLAGS is pushed onto the exit stack: CF, PF, AF, ZF, SF, OF, RF. The remaining bits are left unchanged.

## 37.2 STATE SAVING BY AEX

The State Save Area holds the processor state at the time of an AEX. To allow handling events within the enclave and re-entering it after an AEX, the SSA can be a stack of multiple SSA frames as illustrated in Figure 37-2.

Figure 37-2. The SSA Stack

The location of the SSA frames to be used is controlled by the following variables in the TCS and the SECS:

- Size of a frame in the State Save Area (SECS.SSAFRAMESIZE): This defines the number of 4-KByte pages in a single frame in the State Save Area. The SSA frame size must be large enough to hold the GPR state, the XSAVE state, and the MISC state.
- Base address of the enclave (SECS.BASEADDR): This defines the enclave's base linear address from which the offset to the base of the SSA stack is calculated.
- Number of State Save Area Slots (TCS.NSSA): This defines the total number of slots (frames) in the State Save Area stack.
- Current State Save Area Slot (TCS.CSSA): This defines the slot to use on the next exit.
- State Save Area Offset (TCS.OSSA): This defines the offset of the base address of a set of State Save Area slots from the enclave's base address.

When an AEX occurs, hardware selects the SSA frame to use by examining TCS.CSSA. Processor state is saved into the SSA frame (see Section 37.4) and loaded with a synthetic state (as described in Section 37.3.1) to avoid leaking secrets, RSP and RBP are restored to their values prior to enclave entry, and TCS.CSSA is incremented. As will be described later, if an exception takes the last slot, it will not be possible to reenter the enclave to handle the

exception from within the enclave. A subsequent ERESUME restores the processor state from the current SSA frame and frees the SSA frame.

The format of the XSAVE section of SSA is identical to the format used by the XSAVE/XRSTOR instructions. On EENTER, CSSA must be less than NSSA, ensuring that there is at least one State Save Area slot available for exits. If there is no free SSA frame when executing EENTER, the entry will fail.

## 37.3 SYNTHETIC STATE ON ASYNCHRONOUS ENCLAVE EXIT

### 37.3.1 Processor Synthetic State on Asynchronous Enclave Exit

Table 37-1 shows the synthetic state loaded on AEX. The values shown are the lower 32 bits when the processor is in 32 bit mode and 64 bits when the processor is in 64 bit mode.

**Table 37-1. GPR, x87 Synthetic States on Asynchronous Enclave Exit**

| Register      | Value                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RAX           | 3 (ENCLU[3] is ERESUME).                                                                                                                                                                                                                                                                                                                                                     |
| RBX           | Pointer to TCS of interrupted enclave thread.                                                                                                                                                                                                                                                                                                                                |
| RCX           | AEP of interrupted enclave thread.                                                                                                                                                                                                                                                                                                                                           |
| RDX, RSI, RDI | 0.                                                                                                                                                                                                                                                                                                                                                                           |
| RSP           | Restored from SSA.uRSP.                                                                                                                                                                                                                                                                                                                                                      |
| RBP           | Restored from SSA.uRBP.                                                                                                                                                                                                                                                                                                                                                      |
| R8-R15        | 0 in 64-bit mode; unchanged in 32-bit mode.                                                                                                                                                                                                                                                                                                                                  |
| RIP           | AEP of interrupted enclave thread.                                                                                                                                                                                                                                                                                                                                           |
| RFLAGS        | CF, PF, AF, ZF, SF, OF, RF bits are cleared. All other bits are left unchanged.                                                                                                                                                                                                                                                                                              |
| x87/SSE State | Unless otherwise listed here, all x87 and SSE state are set to the INIT state. The INIT state is the state that would be loaded by the XRSTOR instruction with bits 1:0 both set in the requested feature bitmask (RFBM), and both clear in XSTATE_BV the XSAVE header.                                                                                                      |
| FCW           | On #MF exception: set to 037EH. On all other exits: set to 037FH.                                                                                                                                                                                                                                                                                                            |
| FSW           | On #MF exception: set to 8081H. On all other exits: set to 0H.                                                                                                                                                                                                                                                                                                               |
| MXCSR         | On #XM exception: set to 1F01H. On all other exits: set to 1FB0H.                                                                                                                                                                                                                                                                                                            |
| CR2           | If the event that caused the AEX is a #PF, and the #PF does not directly cause a VM exit, then the low 12 bits are cleared.<br>If the #PF leads directly to a VM exit, CR2 is not updated (usual IA behavior).<br>Note: The low 12 bits are not cleared if a #PF is encountered during the delivery of the EEE that caused the AEX. This is because the #PF was not the EEE. |
| FS, GS        | Restored to values as of most recent EENTER/ERESUME.                                                                                                                                                                                                                                                                                                                         |

### 37.3.2 Synthetic State for Extended Features

When CR4.OSXSAVE = 1, extended features (those controlled by XCR0[63:2]) are set to their respective INIT states when this corresponding bit of SECS.XFRM is set. The INIT state is the state that would be loaded by the XRSTOR instruction had the instruction mask and the XSTATE\_BV field of the XSAVE header each contained the value XFRM. (When the AEX occurs in 32-bit mode, those features that do not exist in 32-bit mode are unchanged.)

### 37.3.3 Synthetic State for MISC Features

State represented by SECS.MISCSELECT might also be overridden by synthetic state after it has been saved into the SSA. State represented by MISCSELECT[0] is not overridden but if the exiting event is a page fault then lower 12 bits of CR2 are cleared.

## 37.4 AEX FLOW

On Enclave Exiting Events (interrupts, exceptions, VM exits or SMIs), the processor state is securely saved inside the enclave, a synthetic state is loaded and the enclave is exited. The EEE then proceeds in the usual exit-defined fashion. The following sections describes the details of an AEX:

1. The exact processor state saved into the current SSA frame depends on whether the enclave is a 32-bit or a 64-bit enclave. In 32-bit mode (IA32\_EFER.LMA = 0 || CS.L = 0), the low 32 bits of the legacy registers (EAX, EBX, ECX, EDX, ESP, EBP, ESI, EDI, EIP, and EFLAGS) are stored. The upper 32 bits of the legacy registers and the 64-bit registers (R8 ... R15) are not stored.

In 64-bit mode (IA32\_EFER.LMA = 1 && CS.L = 1), all 64 bits of the general processor registers (RAX, RBX, RCX, RDX, RSP, RBP, RSI, RDI, R8 ... R15, RIP, and RFLAGS) are stored.

The state of those extended features specified by SECS.ATTRIBUTES.XFRM are stored into the XSAVE area of the current SSA frame. The layout of the x87 and XMM portions (the 1st 512 bytes) depends on the current values of IA32\_EFER.LMA and CS.L:

If IA32\_EFER.LMA = 0 || CS.L = 0, the same format (32-bit) that XSAVE/FXSAVE uses with these values.

If IA32\_EFER.LMA = 1 && CS.L = 1, the same format (64-bit) that XSAVE/FXSAVE uses with these values when REX.W = 1.

The cause of the AEX is saved in the EXITINFO field. See Table 35-10 for details and values of the various fields.

The state of those miscellaneous features (see Section 35.7.2) specified by SECS.MISCSELECT are stored into the MISC area of the current SSA frame.

If CET was enabled in the enclave, then the CET state of the enclave is saved in the CET state save area. If shadow stacks were enabled in the enclave, then the SSP is also saved into the TCS.PREVSSP field.

2. Synthetic state is created for a number of processor registers to present an opaque view of the enclave state. Table 37-1 shows the values for GPRs, x87, SSE, FS, GS, Debug, and performance monitoring on AEX. The synthetic state for other extended features (those controlled by XCR0[62:2]) is set to their respective INIT states when their corresponding bit of SECS.ATTRIBUTES.XFRM is set. The INIT state is that state as defined by the behavior of the XRSTOR instruction when HEADER.XSTATE\_BV[n] is 0. Synthetic state of those miscellaneous features specified by SECS.MISCSELECT depends on the miscellaneous feature. There is no synthetic state required for the miscellaneous state controlled by SECS.MISCSELECT[0].

3. Any code and data breakpoints that were suppressed at the time of enclave entry are unsuppressed when exiting the enclave.
4. RFLAGS.TF is set to the value that it had at the time of the most recent enclave entry (except for the situation that the entry was opt-in for debug; see Section 40.2). In the SSA, RFLAGS.TF is set to 0.
5. RFLAGS.RF is set to 0 in the synthetic state. In the SSA, the value saved is the same as what would have been saved on stack in the non-SGX case (architectural value of RF). Thus, AEXs due to interrupts, traps, and code breakpoints save RF unmodified into SSA, while AEXs due to other faults save RF as 1 in the SSA.

If the event causing AEX happened on intermediate iteration of a REP-prefixed instruction, then RF=1 is saved on SSA, irrespective of its priority.

6. Any performance monitoring activity (including PEBS) or profiling activity (LBR, Tracing using Intel PT) on the exiting thread that was suppressed due to the enclave entry on that thread is unsuppressed. Any counting that had been demoted from AnyThread counting to MyThread counting (on one logical processor) is promoted back to AnyThread counting.
7. The CET state of the enclosing application is restored to the state at the time of the most recent enclave entry, and if CET indirect branch tracking was enabled then the indirect branch tracker is unsuppressed and moved to the WAIT\_FOR\_ENDBRANCH state.

### 37.4.1 AEX Operational Detail

**Temp Variables in AEX Operational Flow**

| Name              | Type              | Size (bits) | Description                                                     |
|-------------------|-------------------|-------------|-----------------------------------------------------------------|
| TMP_RIP           | Effective Address | 32/64       | Address of instruction at which to resume execution on ERESUME. |
| TMP_MODE64        | binary            | 1           | ((IA32_EFER.LMA = 1) && (CS.L = 1)).                            |
| TMP_BRANCH_RECORD | LBR Record        | 2x64        | From/To address to be pushed onto LBR stack.                    |

The pseudo code in this section describes the internal operations that are executed when an AEX occurs in enclave mode. These operations occur just before the normal interrupt or exception processing occurs.

```

(* Save RIP for later use *)
TMP_RIP = Linear Address of Resume RIP
(* Is the processor in 64-bit mode? *)
TMP_MODE64 := ((IA32_EFER.LMA = 1) && (CS.L = 1));

(* Save all registers, When saving EFLAGS, the TF bit is set to 0 and
 the RF bit is set to what would have been saved on stack in the non-SGX case *)

IF (TMP_MODE64 = 0)
 THEN
 Save EAX, EBX, ECX, EDX, ESP, EBP, ESI, EDI, EFLAGS, EIP into the current SSA frame using
 CR_GPR_PA; (* see Table 38-5 for list of CREGs used to describe internal operation within Intel SGX *)

# CHAPTER 38

## INTEL® SGX INSTRUCTION REFERENCES

---

This chapter describes the supervisor and user level instructions provided by Intel® Software Guard Extensions (Intel® SGX). In general, various functionality is encoded as leaf functions within the ENCLS (supervisor), ENCLU (user), and the ENCLV (virtualization operation) instruction mnemonics. Different leaf functions are encoded by specifying an input value in the EAX register of the respective instruction mnemonic.

### 38.1 INTEL® SGX INSTRUCTION SYNTAX AND OPERATION

ENCLS, ENCLU, and ENCLV instruction mnemonics for all leaf functions are covered in this section.

For all instructions, the value of CS.D is ignored; addresses and operands are 64 bits in 64-bit mode and are otherwise 32 bits. Aside from EAX specifying the leaf number as input, each instruction leaf may require all or some subset of the RBX/RCX/RDX as input parameters. Some leaf functions may return data or status information in one or more of the general purpose registers.

#### 38.1.1 ENCLS Register Usage Summary

Table 38-1 summarizes the implicit register usage of supervisor mode enclave instructions.

**Table 38-1. Register Usage of Privileged Enclave Instruction Leaf Functions**

| Instr. Leaf | EAX       | RBX                | RCX              | RDX                 |

### 38.1.5 Internal CREGs

The CREGs as shown in Table 5-4 are hardware specific registers used in this document to indicate values kept by the processor. These values are used while executing in enclave mode or while executing an Intel SGX instruction. These registers are not software visible and are implementation specific. The values in Table 38-5 appear at various places in the pseudo-code of this document. They are used to enhance understanding of the operations.

**Table 38-5. List of Internal CREG**

| Name            | Size (Bits) | Scope |
|-----------------|-------------|-------|
| CR_ENCLAVE_MODE | 1           | LP    |

### 38.1.6 Concurrent Operation Restrictions

Under certain conditions, Intel SGX disallows certain leaf functions from operating concurrently. Listed below are some examples of concurrency that are not allowed.

- For example, Intel SGX disallows the following leafs to concurrently operate on the same EPC page.
  - ECREATE, EADD, and EREMOVE are not allowed to operate on the same EPC page concurrently with themselves.
  - EADD, EEXTEND, and EINIT leaves are not allowed to operate on the same SECS concurrently.
- Intel SGX disallows the EREMOVE leaf from removing pages from an enclave that is in use.
- Intel SGX disallows entry (EENTER and ERESUME) to an enclave while a page from that enclave is being removed.

When disallowed operation is detected, a leaf function may do one of the following:

- Return an SGX\_EPC\_PAGE\_CONFLICT error code in RAX.
- Cause a #GP(0) exception.

To prevent such exceptions, software must serialize leaf functions or prevent these leaf functions from accessing the same EPC page.

#### 38.1.6.1 Concurrency Tables of Intel® SGX Instructions

The tables below detail the concurrent operation restrictions of all SGX leaf functions. For each leaf function, the table has a separate line for each of the EPC pages the leaf function accesses.

For each such EPC page, the base concurrency requirements are detailed as follows:

- **Exclusive Access** means that no other leaf function that requires either shared or exclusive access to the same EPC page may be executed concurrently. For example, EADD requires an exclusive access to the target page it accesses.

- **Shared Access** means that no other leaf function that requires an exclusive access to the same EPC page may be executed concurrently. Other leaf functions that require shared access may run concurrently. For example, EADD requires a shared access to the SECS page it accesses.
- **Concurrent Access** means that any other leaf function that requires any access to the same EPC page may be executed concurrently. For example, EGETKEY has no concurrency requirements for the KEYREQUEST page.

In addition to the base concurrency requirements, additional concurrency requirements are listed, which apply only to specific sets of leaf functions. For example, there are additional requirements that apply for EADD, EXTEND, and EINIT. EADD and EEXTEND can't execute concurrently on the same SECS page.

The tables also detail the leaf function's behavior when a conflict happens, i.e., a concurrency requirement is not met. In this case, the leaf function may return an SGX\_EPC\_PAGE\_CONFLICT error code in RAX, or it may cause an exception. In addition, the tables detail those conflicts where a VM Exit may be triggered, and list the Exit Qualification code that is provided in such cases.

**Table 38-6. Base Concurrency Restrictions**

| Leaf           | Parameter  | Base Concurrency Restrictions |             |                                    |
|----------------|------------|-------------------------------|-------------|------------------------------------|
|                |            | Access                        | On Conflict | SGX_CONFLICT VM Exit Qualification |

| Z0    | NA        | NA        | NA        | See Section 38.3           |

#### Description

The ENCLS instruction invokes the specified privileged Intel SGX leaf function for managing and debugging enclaves. Software specifies the leaf function by setting the appropriate value in the register EAX as input. The registers RBX, RCX, and RDX have leaf-specific purpose, and may act as input, as output, or may be unused. In 64-bit mode, the instruction ignores upper 32 bits of the RAX register.

The ENCLS instruction produces an invalid-opcode exception (#UD) if CR0.PE = 0 or RFLAGS.VM = 1, or if it is executed in system-management mode (SMM). Additionally, any attempt to execute the instruction when CPL > 0 results in #UD. The instruction produces a general-protection exception (#GP) if CR0.PG = 0 or if an attempt is made to invoke an undefined leaf function.

In VMX non-root operation, execution of ENCLS may cause a VM exit if the “enable ENCLS exiting” VM-execution control is 1. In this case, execution of individual leaf functions of ENCLS is governed by the ENCLS-exiting bitmap field in the VMCS. Each bit in that field corresponds to the index of an ENCLS leaf function (as provided in EAX).

Software in VMX root operation can thus intercept the invocation of various ENCLS leaf functions in VMX non-root operation by setting the “enable ENCLS exiting” VM-execution control and setting the corresponding bits in the ENCLS-exiting bitmap.

Addresses and operands are 32 bits outside 64-bit mode (IA32\_EFER.LMA = 0 || CS.L = 0) and are 64 bits in 64-bit mode (IA32\_EFER.LMA = 1 || CS.L = 1). CS.D value has no impact on address calculation. The DS segment is used to create linear addresses.

Segment override prefixes and address-size override prefixes are ignored, and is the REX prefix in 64-bit mode.

#### Operation

```

IF TSX_ACTIVE
 THEN GOTO TSX_ABORT_PROCESSING; Fl;

IF CRO.PE = 0 or RFLAGS.VM = 1 or in SMM or CPUID.SGX_LEAF.0:EAX.SE1 = 0
 THEN #UD; Fl;

IF (CPL > 0)
 THEN #UD; Fl;

IF in VMX non-root operation and the “enable ENCLS exiting” VM-execution control is 1
 THEN
 IF EAX < 63 and ENCLS_exiting_bitmap[EAX] = 1 or EAX > 62 and ENCLS_exiting_bitmap[63] = 1
 THEN VM exit;
 Fl;
 Fl;

IF IA32_FEATURE_CONTROL.LOCK = 0 or IA32_FEATURE_CONTROL.SGX_ENABLE = 0
 THEN #GP(0); Fl;

IF (EAX is an invalid leaf number)
 THEN #GP(0); Fl;

```

```

IF CRO.PG = 0
 THEN #GP(0); Fl;
(* DS must not be an expanded down segment *)
IF not in 64-bit mode and DS.Type is expand-down data
 THEN #GP(0); Fl;

```

| Z0    | NA        | NA        | NA        | See Section 38.4           |

### Description

The ENCLU instruction invokes the specified non-privileged Intel SGX leaf functions. Software specifies the leaf function by setting the appropriate value in the register EAX as input. The registers RBX, RCX, and RDX have leaf-specific purpose, and may act as input, as output, or may be unused. In 64-bit mode, the instruction ignores upper 32 bits of the RAX register.

The ENCLU instruction produces an invalid-opcode exception (#UD) if CR0.PE = 0 or RFLAGS.VM = 1, or if it is executed in system-management mode (SMM). Additionally, any attempt to execute this instruction when CPL < 3 results in #UD. The instruction produces a general-protection exception (#GP) if either CR0.PG or CR0.NE is 0, or if an attempt is made to invoke an undefined leaf function. The ENCLU instruction produces a device not available exception (#NM) if CR0.TS = 1.

Addresses and operands are 32 bits outside 64-bit mode (IA32\_EFER.LMA = 0 or CS.L = 0) and are 64 bits in 64-bit mode (IA32\_EFER.LMA = 1 and CS.L = 1). CS.D value has no impact on address calculation. The DS segment is used to create linear addresses.

Segment override prefixes and address-size override prefixes are ignored, as is the REX prefix in 64-bit mode.

| Z0    | NA        | NA        | NA        | See Section 38.3           |

**Description**

The ENCLV instruction invokes the virtualization SGX leaf functions for managing enclaves in a virtualized environment. Software specifies the leaf function by setting the appropriate value in the register EAX as input. The registers RBX, RCX, and RDX have leaf-specific purpose, and may act as input, as output, or may be unused. In non 64-bit mode, the instruction ignores upper 32 bits of the RAX register.

The ENCLV instruction produces an invalid-opcode exception (#UD) if CR0.PE = 0 or RFLAGS.VM = 1, if it is executed in system-management mode (SMM), or not in VMX operation. Additionally, any attempt to execute the instruction when CPL > 0 results in #UD. The instruction produces a general-protection exception (#GP) if CR0.PG = 0 or if an attempt is made to invoke an undefined leaf function.

Software in VMX root mode of operation can enable execution of the ENCLV instruction in VMX non-root mode by setting enable ENCLV execution control in the VMCS. If enable ENCLV execution control in the VMCS is clear, execution of the ENCLV instruction in VMX non-root mode results in #UD.

When execution of ENCLV instruction in VMX non-root mode is enabled, software in VMX root operation can intercept the invocation of various ENCLV leaf functions in VMX non-root operation by setting the corresponding bits in the ENCLV-exiting bitmap.

Addresses and operands are 32 bits in 32-bit mode (IA32\_EFER.LMA == 0 || CS.L == 0) and are 64 bits in 64-bit mode (IA32\_EFER.LMA == 1 && CS.L == 1). CS.D value has no impact on address calculation.

Segment override prefixes and address-size override prefixes are ignored, as is the REX prefix in 64-bit mode.

### 38.3 INTEL® SGX SYSTEM LEAF FUNCTION REFERENCE

Leaf functions available with the ENCLS instruction mnemonic are covered in this section. In general, each instruction leaf requires EAX to specify the leaf function index and/or additional implicit registers specifying leaf-specific input parameters. An instruction operand encoding table provides details of each implicit register usage and associated input/output semantics.

In many cases, an input parameter specifies an effective address associated with a memory object inside or outside the EPC, the memory addressing semantics of these memory objects are also summarized in a separate table.

## EADD—Add a Page to an Uninitialized Enclave

| Opcode/<br>Instruction   | Op/En | 64/32<br>bit Mode<br>Support | CPUID<br>Feature<br>Flag | Description                                                 |

| IR    | EADD (In) | Address of a PAGEINFO (In) | Address of the destination EPC page (In) |

#### Description

This leaf function copies a source page from non-enclave memory into the EPC, associates the EPC page with an SECS page residing in the EPC, and stores the linear address and security attributes in EPCM. As part of the association, the enclave offset and the security attributes are measured and extended into the SECS.MRENCLAVE. This instruction can only be executed when current privilege level is 0.

RBX contains the effective address of a PAGEINFO structure while RCX contains the effective address of an EPC page. The table below provides additional information on the memory parameter of EADD leaf function.

### EADD Memory Parameter Semantics

### Instruction Operand Encoding

| Op/En | EAX       | RBX                       | RCX                                      |
|-------|-----------|---------------------------|------------------------------------------|
| IR    | EAUG (In) | Address of a SECINFO (In) | Address of the destination EPC page (In) |

### Description

This leaf function zeroes a page of EPC memory, associates the EPC page with an SECS page residing in the EPC, and stores the linear address and security attributes in the EPCM. As part of the association, the security attributes are configured to prevent access to the EPC page until a corresponding invocation of the EACCEPT leaf or EACCEPT-COPY leaf confirms the addition of the new page into the enclave. This instruction can only be executed when current privilege level is 0.

RBX contains the effective address of a PAGEINFO structure while RCX contains the effective address of an EPC page. The table below provides additional information on the memory parameter of the EAUG leaf function.

### EAUG Memory Parameter Semantics

| PAGEINFO                             | PAGEINFO.Secs                          | PAGEINFO.SRCPGE | PAGEINFO.SECINFO                     | EPCPAGE                           |
|--------------------------------------|----------------------------------------|-----------------|--------------------------------------|-----------------------------------|
| Read access permitted by Non Enclave | Read/Write access permitted by Enclave | Must be zero    | Read access permitted by Non Enclave | Write access permitted by Enclave |

The instruction faults if any of the following:

### EAUG Faulting Conditions

|                                           |                                                                       |
|-------------------------------------------|-----------------------------------------------------------------------|
| The operands are not properly aligned.    | Unsupported security attributes are set.                              |
| Refers to an invalid SECS.                | Reference is made to an SECS that is locked by another thread.        |
| The EPC page is locked by another thread. | RCX does not contain an effective address of an EPC page.             |
| The EPC page is already valid.            | The specified enclave offset is outside of the enclave address space. |
| The SECS has been initialized.            |                                                                       |

### Concurrency Restrictions

Table 38-10. Base Concurrency Restrictions of EAUG

| Leaf | Parameter                  | Base Concurrency Restrictions |             |                                    |
|------|----------------------------|-------------------------------|-------------|------------------------------------|

### Instruction Operand Encoding

| Op/En | EBLOCK (In) |                         | RCX                                    |
|-------|-------------|-------------------------|----------------------------------------|
| IR    |             | Return error code (Out) | Effective address of the EPC page (In) |

#### Description

This leaf function causes an EPC page to be marked as BLOCKED. This instruction can only be executed when current privilege level is 0.

The content of RCX is an effective address of an EPC page. The DS segment is used to create linear address. Segment override is not supported.

An error code is returned in RAX.

The table below provides additional information on the memory parameter of EBLOCK leaf function.

### EBLOCK Memory Parameter Semantics

|                                        |
|----------------------------------------|
| EPPCPAGE                               |
| Read/write access permitted by Enclave |

The error codes are:

**Table 38-12. EBLOCK Return Value in RAX**

| Error Code (see Table 38-4) | Description                                                                                                                                                                                                                 |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No Error                    | EBLOCK successful.                                                                                                                                                                                                          |
| SGX_BLKSTATE                | Page already blocked. This value is used to indicate to a VMM that the page was already in BLOCKED state as a result of EBLOCK and thus will need to be restored to this state when it is eventually reloaded (using ELDB). |
| SGX_ENTRYEPOCH_LOCKED       | SECS locked for Entry Epoch update. This value indicates that an ETRACK is currently executing on the SECS. The EBLOCK should be reattempted.                                                                               |
| SGX_NOTBLOCKABLE            | Page type is not one which can be blocked.                                                                                                                                                                                  |
| SGX_PG_INVLD                | Page is not valid and cannot be blocked.                                                                                                                                                                                    |
| SGX_EPC_PAGE_CONFLICT       | Page is being written by EADD, EAUG, ECREATE, ELDU/B, EMODT, or EWB.                                                                                                                                                        |

#### Concurrency Restrictions

| IR    | ECREATE (In) | Address of a PAGEINFO (In) | Address of the destination SECS page (In) |

### Description

ENCLS[ECREATE] is the first instruction executed in the enclave build process. ECREATE copies an SECS structure outside the EPC into an SECS page inside the EPC. The internal structure of SECS is not accessible to software.

ECREATE will set up fields in the protected SECS and mark the page as valid inside the EPC. ECREATE initializes or checks unused fields.

Software sets the following fields in the source structure: SECS:BASEADDR, SECS:SIZE in bytes, ATTRIBUTES, CONFIGID, and CONFIGSVN. SECS:BASEADDR must be naturally aligned on an SECS.SIZE boundary. SECS.SIZE must be at least 2 pages (8192).

The source operand RBX contains an effective address of a PAGEINFO structure. PAGEINFO contains an effective address of a source SECS and an effective address of an SECINFO. The SECS field in PAGEINFO is not used.

The RCX register is the effective address of the destination SECS. It is an address of an empty slot in the EPC. The SECS structure must be page aligned. SECINFO flags must specify the page as an SECS page.

### ECREATE Memory Parameter Semantics

| PAGEINFO                             | PAGEINFO.SRCPGE                      | PAGEINFO.SECINFO                     | EPCPAGE                           |
|--------------------------------------|--------------------------------------|--------------------------------------|-----------------------------------|
| Read access permitted by Non Enclave | Read access permitted by Non Enclave | Read access permitted by Non Enclave | Write access permitted by Enclave |

ECREATE will fault if the SECS target page is in use; already valid; outside the EPC. It will also fault if addresses are not aligned; unused PAGEINFO fields are not zero.

If the amount of space needed to store the SSA frame is greater than the amount specified in SECS.SSAFRAME-SIZE, a #GP(0) results. The amount of space needed for an SSA frame is computed based on DS:TMP\_SECS.ATTRIBUTES.XFRM size. Details of computing the size can be found Section 39.7.

### Concurrency Restrictions

Table 38-15. Base Concurrency Restrictions of ECREATE

| Leaf    | Parameter     | Base Concurrency Restrictions |             |                                    |
|---------|---------------|-------------------------------|-------------|------------------------------------|
|         |               | Access                        | On Conflict | SGX_CONFLICT VM Exit Qualification |
| ECREATE | SECS [DS:RCX] | Exclusive                     | #GP         | EPC_PAGE_CONFLICT_EXCEPTION        |

**Description**

This leaf function copies a quadword/doubleword from an EPC page belonging to a debug enclave into the RBX register. Eight bytes are read in 64-bit mode, four bytes are read in non-64-bit modes. The size of data read cannot be overridden.

The effective address of the source location inside the EPC is provided in the register RCX.

**EDBGRD Memory Parameter Semantics**

|-----------------------------|---------------------------------------------------------------------------------|
| No Error                    | EDBGRD successful.                                                              |
| SGX_PAGE_NOT_DEBUGGABLE     | The EPC page cannot be accessed because it is in the PENDING or MODIFIED state. |

The instruction faults if any of the following:

**EDBGRD Faulting Conditions**

|                                                                                |                                                                                                         |
|--------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| RCX points into a page that is an SECS.                                        | RCX does not resolve to a naturally aligned linear address.                                             |
| RCX points to a page that does not belong to an enclave that is in debug mode. | RCX points to a location inside a TCS that is beyond the architectural size of the TCS (SGX_TCS_LIMIT). |
| An operand causing any segment violation.                                      | May page fault.                                                                                         |
| CPL > 0.                                                                       |                                                                                                         |

This instruction ignores the EPCM RWX attributes on the enclave page. Consequently, violation of EPCM RWX attributes via EDBGRD does not result in a #GP.

## Concurrency Restrictions

### Flags Affected

ZF is set if the page is MODIFIED or PENDING; RAX contains the error code. Otherwise ZF is cleared and RAX is set to 0. CF, PF, AF, OF, SF are cleared.

### Protected Mode Exceptions

- #GP(0)      If the address in RCS violates DS limit or access rights.  
                 If DS segment is unusable.  
                 If RCX points to a memory location not 4Byte-aligned.  
                 If the address in RCX points to a page belonging to a non-debug enclave.  
                 If the address in RCX points to a page which is not PT\_TCS, PT\_REG or PT\_VA.  
                 If the address in RCX points to a location inside TCS that is beyond SGX\_TCS\_LIMIT.

#PF(error code) If a page fault occurs in accessing memory operands.  
If the address in RCX points to a non-EPC page.  
If the address in RCX points to an invalid EPC page.

#### 64-Bit Mode Exceptions

#GP(0) If RCX is non-canonical form.  
If RCX points to a memory location not 8Byte-aligned.  
If the address in RCX points to a page belonging to a non-debug enclave.  
If the address in RCX points to a page which is not PT\_TCS, PT\_REG or PT\_VA.  
If the address in RCX points to a location inside TCS that is beyond SGX\_TCS\_LIMIT.

#PF(error code) If a page fault occurs in accessing memory operands.  
If the address in RCX points to a non-EPC page.  
If the address in RCX points to an invalid EPC page.

**Description**

This leaf function copies the content in EBX/RBX to an EPC page belonging to a debug enclave. Eight bytes are written in 64-bit mode, four bytes are written in non-64-bit modes. The size of data cannot be overridden.

The effective address of the target location inside the EPC is provided in the register RCX.

**EDBGWR Memory Parameter Semantics**

|  |                                   |
|--|-----------------------------------|
|  | EPCQW                             |
|  | Write access permitted by Enclave |

The instruction faults if any of the following:

**EDBGWR Faulting Conditions**

|                                                                                |                                                                   |
|--------------------------------------------------------------------------------|-------------------------------------------------------------------|
| RCX points into a page that is an SECS.                                        | RCX does not resolve to a naturally aligned linear address.       |
| RCX points to a page that does not belong to an enclave that is in debug mode. | RCX points to a location inside a TCS that is not the FLAGS word. |
| An operand causing any segment violation.                                      | May page fault.                                                   |
| CPL > 0.                                                                       |                                                                   |

The error codes are:

**Table 38-20. EDBGWR Return Value in RAX**

| Error Code (see Table 38-4) | Description                                                                     |
|-----------------------------|---------------------------------------------------------------------------------|
| No Error                    | EDBGWR successful.                                                              |
| SGX_PAGE_NOT_DEBUGGABLE     | The EPC page cannot be accessed because it is in the PENDING or MODIFIED state. |

This instruction ignores the EPCM RWX attributes on the enclave page. Consequently, violation of EPCM RWX attributes via EDBGWR does not result in a #GP.

|-------|--------------|------------------------------------------------------|-------------------------------------------------------|
| IR    | EEXTEND (In) | Effective address of the SECS of the data chunk (In) | Effective address of a 256-byte chunk in the EPC (In) |

**Description**

This leaf function updates the MRENCLAVE measurement register of an SECS with the measurement of an EXTEND string compromising of "EEXTEND" || ENCLAVEOFFSET || PADDING || 256 bytes of the enclave page. This instruction can only be executed when current privilege level is 0 and the enclave is uninitialized.

RBX contains the effective address of the SECS of the region to be measured. The address must be the same as the one used to add the page into the enclave.

RCX contains the effective address of the 256 byte region of an EPC page to be measured. The DS segment is used to create linear addresses. Segment override is not supported.

|-------|------------|------------------|---------------------------|----------------------|----------------------------|
| IR    | EINIT (In) | Error code (Out) | Address of SIGSTRUCT (In) | Address of SECS (In) | Address of EINITTOKEN (In) |

### Description

This leaf function is the final instruction executed in the enclave build process. After EINIT, the MRENCLAVE measurement is complete, and the enclave is ready to start user code execution using the EENTER instruction.

EINIT takes the effective address of a SIGSTRUCT and EINITTOKEN. The SIGSTRUCT describes the enclave including MRENCLAVE, ATTRIBUTES, ISVSVN, a 3072 bit RSA key, and a signature using the included key.

SIGSTRUCT must be populated with two values, q1 and q2. These are calculated using the formulas shown below:

$$q1 = \text{floor}(\text{Signature}^2 / \text{Modulus});$$

$$q2 = \text{floor}((\text{Signature}^3 - q1 * \text{Signature} * \text{Modulus}) / \text{Modulus});$$

The EINITTOKEN contains the MRENCLAVE, MRSIGNER, and ATTRIBUTES. These values must match the corresponding values in the SECS. If the EINITTOKEN was created with a debug launch key, the enclave must be in debug mode as well.

Figure 38-1. Relationships Between SECS, SIGSTRUCT, and EINITTOKEN

**EINIT Memory Parameter Semantics**

| SIGSTRUCT             | SECS                         | EINITTOKEN            |
|-----------------------|------------------------------|-----------------------|
| Access by non-Enclave | Read/Write access by Enclave | Access by non-Enclave |

EINIT performs the following steps, which can be seen in Figure 38-1:

1. Validates that SIGSTRUCT is signed using the enclosed public key.
2. Checks that the completed computation of SECS.MRENCLAVE equals SIGSTRUCT.HASHENCLAVE.
3. Checks that no controlled ATTRIBUTES bits are set in SIGSTRUCT.ATTRIBUTES unless the SHA256 digest of SIGSTRUCT.MODULUS equals IA32\_SGX\_LEPUBKEYHASH.
4. Checks that the result of bitwise and-ing SIGSTRUCT.ATTRIBUTEMASK with SIGSTRUCT.ATTRIBUTES equals the result of bitwise and-ing SIGSTRUCT.ATTRIBUTEMASK with SECS.ATTRIBUTES.
5. If EINITTOKEN.VALID is 0, checks that the SHA256 digest of SIGSTRUCT.MODULUS equals IA32\_SGX\_LEPUBKEYHASH.
6. If EINITTOKEN.VALID is 1, checks the validity of EINITTOKEN.
7. If EINITTOKEN.VALID is 1, checks that EINITTOKEN.MRENCLAVE equals SECS.MRENCLAVE.
8. If EINITTOKEN.VALID is 1 and EINITTOKEN.ATTRIBUTES.DEBUG is 1, SECS.ATTRIBUTES.DEBUG must be 1.
9. Commits SECS.MRENCLAVE, and sets SECS.MRSIGNER, SECS.ISVSVN, and SECS.ISVPRODID based on SIGSTRUCT.
10. Update the SECS as Initialized.

Periodically, EINIT polls for certain asynchronous events. If such an event is detected, it completes with failure code (ZF=1 and RAX = SGX\_UNMASKED\_EVENT), and RIP is incremented to point to the next instruction. These events includes external interrupts, non-maskable interrupts, system-management interrupts, machine checks, INIT signals, and the VMX-preemption timer. EINIT does not fail if the pending event is inhibited (e.g., external interrupts could be inhibited due to blocking by MOV SS blocking or by STI).

The following bits in RFLAGS are cleared: CF, PF, AF, OF, and SF. When the instruction completes with an error, RFLAGS.ZF is set to 1, and the corresponding error bit is set in RAX. If no error occurs, RFLAGS.ZF is cleared and RAX is set to 0.

The error codes are:

**Table 38-25. EINIT Return Value in RAX**

| Error Code (see Table 38-4) | Description                                                                                         |
|-----------------------------|-----------------------------------------------------------------------------------------------------|
| No Error                    | EINIT successful.                                                                                   |
| SGX_INVALID_SIG_STRUCT      | If SIGSTRUCT contained an invalid value.                                                            |
| SGX_INVALID_ATTRIBUTE       | If SIGSTRUCT contains an unauthorized attributes mask.                                              |
| SGX_INVALID_MEASUREMENT     | If SIGSTRUCT contains an incorrect measurement.<br>If EINITTOKEN contains an incorrect measurement. |
| SGX_INVALID_SIGNATURE       | If signature does not validate with enclosed public key.                                            |
| SGX_INVALID_LICENSE         | If license is invalid.                                                                              |
| SGX_INVALID_CPVUSVN         | If license SVN is unsupported.                                                                      |
| SGX_UNMASKED_EVENT          | If an unmasked event is received before the instruction completes its operation.                    |

### Instruction Operand Encoding

| Op/En | EAX               |                            | RBX                             | RCX                             | RDX                                        |
|-------|-------------------|----------------------------|---------------------------------|---------------------------------|--------------------------------------------|
| IR    | ELDB/ELDU<br>(In) | Return error<br>code (Out) | Address of the PAGEINFO<br>(In) | Address of the EPC page<br>(In) | Address of the version-<br>array slot (In) |

### Description

This leaf function copies a page from regular main memory to the EPC. As part of the copying process, the page is cryptographically authenticated and decrypted. This instruction can only be executed when current privilege level is 0.

The ELDB leaf function sets the BLOCK bit in the EPCM entry for the destination page in the EPC after copying. The ELDU leaf function clears the BLOCK bit in the EPCM entry for the destination page in the EPC after copying.

RBX contains the effective address of a PAGEINFO structure; RCX contains the effective address of the destination EPC page; RDX holds the effective address of the version array slot that holds the version of the page.

The ELDBC/ELDUC leafs are very similar to ELDB and ELDU. They provide an error code on the concurrency conflict for any of the pages which need to acquire a lock. These include the destination, SECS, and VA slot.

The table below provides additional information on the memory parameter of ELDB/ELDU leaf functions.

### ELDB/ELDU/ELDBC/ELBUC Memory Parameter Semantics

| PAGEINFO                   | PAGEINFO.SRCPGE            | PAGEINFO.PCMD              | PAGEINFO.SECS                | EPCPAGE                                   | Version-Array Slot                          |
|----------------------------|----------------------------|----------------------------|------------------------------|-------------------------------------------|---------------------------------------------|
| Non-enclave<br>read access | Non-enclave read<br>access | Non-enclave read<br>access | Enclave read/write<br>access | Read/Write access<br>permitted by Enclave | Read/Write access per-<br>mitted by Enclave |

The error codes are:

**Table 38-28. ELDB/ELDU/ELDBC/ELBUC Return Value in RAX**

| Error Code (see Table 38-4) | Description             |
|-----------------------------|-------------------------|
| No Error                    | ELDB/ELDU successful.   |
| SGX_MAC_COMPARE_FAIL        | If the MAC check fails. |

## Concurrency Restrictions

**Table 38-29. Base Concurrency Restrictions of ELDB/ELDU/ELDBC/ELBUC**

| Leaf        | Parameter                  | Base Concurrency Restrictions |                       |                                    |

### Flags Affected

Sets ZF if unsuccessful, otherwise cleared and RAX returns error code. Clears CF, PF, AF, OF, SF.

**Protected Mode Exceptions**

- #GP(0) If a memory operand effective address is outside the DS segment limit.  
If a memory operand is not properly aligned.  
If the instruction's EPC resource is in use by others.  
If the instruction fails to verify MAC.  
If the version-array slot is in use.  
If the parameters fail consistency checks.
- #PF(error code) If a page fault occurs in accessing memory operands.  
If a memory operand expected to be in EPC does not resolve to an EPC page.  
If one of the EPC memory operands has incorrect page type.  
If the destination EPC page is already valid.

**64-Bit Mode Exceptions**

- #GP(0) If a memory operand is non-canonical form.  
If a memory operand is not properly aligned.  
If the instruction's EPC resource is in use by others.  
If the instruction fails to verify MAC.  
If the version-array slot is in use.  
If the parameters fail consistency checks.
- #PF(error code) If a page fault occurs in accessing memory operands.  
If a memory operand expected to be in EPC does not resolve to an EPC page.  
If one of the EPC memory operands has incorrect page type.  
If the destination EPC page is already valid.

## EMODPR—Restrict the Permissions of an EPC Page

### Instruction Operand Encoding

| Op/En | EAX         |                         | RBX                       | RCX                                      |
|-------|-------------|-------------------------|---------------------------|------------------------------------------|
| IR    | EMODPR (In) | Return Error Code (Out) | Address of a SECINFO (In) | Address of the destination EPC page (In) |

#### Description

This leaf function restricts the access rights associated with an EPC page in an initialized enclave. THE RWX bits of the SECINFO parameter are treated as a permissions mask; supplying a value that does not restrict the page permissions will have no effect. This instruction can only be executed when current privilege level is 0.

RBX contains the effective address of a SECINFO structure while RCX contains the effective address of an EPC page. The table below provides additional information on the memory parameter of the EMODPR leaf function.

### EMODPR Memory Parameter Semantics

| SECINFO                              | EPCPAGE                                |
|--------------------------------------|----------------------------------------|
| Read access permitted by Non Enclave | Read/Write access permitted by Enclave |

The instruction faults if any of the following:

### EMODPR Faulting Conditions

|                                           |                                                                                  |
|-------------------------------------------|----------------------------------------------------------------------------------|
| The operands are not properly aligned.    | If unsupported security attributes are set.                                      |
| The Enclave is not initialized.           | SECS is locked by another thread.                                                |
| The EPC page is locked by another thread. | RCX does not contain an effective address of an EPC page in the running enclave. |
| The EPC page is not valid.                |                                                                                  |

The error codes are:

Table 38-31. EMODPR Return Value in RAX

| Error Code (see Table 38-4) | Description                                                                     |
|-----------------------------|---------------------------------------------------------------------------------|
| No Error                    | EMODPR successful.                                                              |

## EPA—Add Version Array

| Opcode/<br>Instruction  | Op/En | 64/32<br>bit Mode<br>Support | CPUID<br>Feature<br>Flag | Description                                         |
|-------------------------|-------|------------------------------|--------------------------|-----------------------------------------------------|
| EAX = OAH<br>ENCLS[EPA] | IR    | V/V                          | SGX1                     | This leaf function adds a Version Array to the EPC. |

### Instruction Operand Encoding

|       |          |                      |                                        |
|-------|----------|----------------------|----------------------------------------|
| Op/En | EAX      | RBX                  | RCX                                    |
| IR    | EPA (In) | PT_VA (In, Constant) | Effective address of the EPC page (In) |

#### Description

This leaf function creates an empty version array in the EPC page whose logical address is given by DS:RCX, and sets up EPCM attributes for that page. At the time of execution of this instruction, the register RBX must be set to PT\_VA.

The table below provides additional information on the memory parameter of EPA leaf function.

### EPA Memory Parameter Semantics

|                                   |
|-----------------------------------|
| EPCPAGE                           |
| Write access permitted by Enclave |

#### Concurrency Restrictions

**Table 38-37. Base Concurrency Restrictions of EPA**

| Leaf | Parameter   | Base Concurrency Restrictions |             |                                    |
|------|-------------|-------------------------------|-------------|------------------------------------|
|      |             | Access                        | On Conflict | SGX_CONFLICT VM Exit Qualification |
| EPA  | VA [DS:RCX] | Exclusive                     | #GP         | EPC_PAGE_CONFLICT_EXCEPTION        |

**Table 38-38. Additional Concurrency Restrictions of EPA**

| Leaf | Parameter   | Additional Concurrency Restrictions                |             |                          |             |                     |             |
|------|-------------|----------------------------------------------------|-------------|--------------------------|-------------|---------------------|-------------|
|      |             | vs. EACCEPT, EACCEPTCOPY,<br>EMODPE, EMODPR, EMODT |             | vs. EADD, EEXTEND, EINIT |             | vs. ETRACK, ETRACKC |             |
|      |             | Access                                             | On Conflict | Access                   | On Conflict | Access              | On Conflict |
| EPA  | VA [DS:RCX] | Concurrent                                         | L           | Concurrent               |             | Concurrent          |             |

#### Operation

IF (RBX ≠ PT\_VA or DS:RCX is not 4KByte Aligned)

THEN #GP(0); Fl;

IF (DS:RCX does not resolve within an EPC)

THEN #PF(DS:RCX); Fl;

(\* Check concurrency with other Intel SGX instructions \*)

IF (Other Intel SGX instructions accessing the page)

THEN

IF (<<VMX non-root operation>> AND <<ENABLE\_EPC\_VIRTUALIZATION\_EXTENSIONS>>)

```

THEN
 VMCS.Exit_reason := SGX_CONFLICT;

EPCM(DS:RCX).MODIFIED := 0;
EPCM(DS:RCX).PR := 0;
EPCM(DS:RCX).RWX := 0;
EPCM(DS:RCX).VALID := 1;

```

**Flags Affected**

None

**Protected Mode Exceptions**

- #GP(0)      If a memory operand effective address is outside the DS segment limit.  
                 If a memory operand is not properly aligned.  
                 If another Intel SGX instruction is accessing the EPC page.  
                 If RBX is not set to PT\_VA.
- #PF(error code)      If a page fault occurs in accessing memory operands.  
                 If a memory operand is not an EPC page.  
                 If the EPC page is valid.

**64-Bit Mode Exceptions**

- #GP(0)      If a memory operand is non-canonical form.  
                 If a memory operand is not properly aligned.  
                 If another Intel SGX instruction is accessing the EPC page.  
                 If RBX is not set to PT\_VA.
- #PF(error code)      If a page fault occurs in accessing memory operands.  
                 If a memory operand is not an EPC page.  
                 If the EPC page is valid.

## ERDINFO—Read Type and Status Information About an EPC Page

| Opcode/<br>Instruction      | Op/En | 64/32<br>bit Mode<br>Support | CPUID<br>Feature<br>Flag | Description                                                               |
|-----------------------------|-------|------------------------------|--------------------------|---------------------------------------------------------------------------|
| EAX = 10H<br>ENCLS[ERDINFO] | IR    | V/V                          | EAX[6]                   | This leaf function returns type and status information about an EPC page. |

### Instruction Operand Encoding

| Op/En | EAX          |                            | RBX                                | RCX                                         |
|-------|--------------|----------------------------|------------------------------------|---------------------------------------------|
| IR    | ERDINFO (In) | Return error code<br>(Out) | Address of a RDINFO structure (In) | Address of the destination EPC page<br>(In) |

#### Description

This instruction reads type and status information about an EPC page and returns it in a RDINFO structure. The STATUS field of the structure describes the status of the page and determines the validity of the remaining fields. The FLAGS field returns the EPCM permissions of the page; the page type; and the BLOCKED, PENDING, MODIFIED, and PR status of the page. For enclave pages, the ENCLAVECONTEXT field of the structure returns the value of SECS.ENCLAVECONTEXT. For non-enclave pages (e.g., VA) ENCLAVECONTEXT returns 0.

For invalid or non-EPC pages, the instruction returns an information code indicating the page's status, in addition to populating the STATUS field.

ERDINFO returns an error code if the destination EPC page is being modified by a concurrent SGX instruction.

RBX contains the effective address of a RDINFO structure while RCX contains the effective address of an EPC page. The table below provides additional information on the memory parameter of ERDINFO leaf function.

### ERDINFO Memory Parameter Semantics

| RDINFO                                     | EPCPAGE                          |

|-------|--------------|-------------------------|----------------------------------------|
| IR    | EREMOVE (In) | Return error code (Out) | Effective address of the EPC page (In) |

#### Description

This leaf function causes an EPC page to be un-associated with its SECS and be marked as unused. This instruction leaf can only be executed when the current privilege level is 0.

The content of RCX is an effective address of an EPC page. The DS segment is used to create linear address. Segment override is not supported.

The instruction fails if the operand is not properly aligned or does not refer to an EPC page or the page is in use by another thread, or other threads are running in the enclave to which the page belongs. In addition the instruction fails if the operand refers to an SECS with associations.

### EREMOVE Memory Parameter Semantics

| IR    | ETRACK<br>(In) | Return error code (Out) | Address of the destination EPC page<br>(In, EA) | Address of the SECS page (In, EA) |

### Description

The ETRACKC instruction is thread safe variant of ETRACK leaf and can be executed concurrently with other CPU threads operating on the same SECS.

This leaf function provides the mechanism for hardware to track that software has completed the required TLB address clears successfully. The instruction can only be executed when the current privilege level is 0.

The content of RCX is an effective address of an EPC page.

The table below provides additional information on the memory parameter of ETRACK leaf function.

### ETRACKC Memory Parameter Semantics

|                                        |
|----------------------------------------|
| EPCPAGE                                |
| Read/Write access permitted by Enclave |

The error codes are:

Table 38-48. ETRACKC Return Value in RAX

## 38.4 INTEL® SGX USER LEAF FUNCTION REFERENCE

Leaf functions available with the ENCLU instruction mnemonic are covered in this section. In general, each instruction leaf requires EAX to specify the leaf function index and/or additional registers specifying leaf-specific input parameters. An instruction operand encoding table provides details of the implicitly-encoded register usage and associated input/output semantics.

In many cases, an input parameter specifies an effective address associated with a memory object inside or outside the EPC, the memory addressing semantics of these memory objects are also summarized in a separate table.

**EACCEPT—Accept Changes to an EPC Page**

| Opcode/<br>Instruction      | Op/En | 64/32<br>bit Mode<br>Support | CPUID<br>Feature<br>Flag | Description                                                                                       |
|-----------------------------|-------|------------------------------|--------------------------|---------------------------------------------------------------------------------------------------|
| EAX = 05H<br>ENCLU[EACCEPT] | IR    | V/V                          | SGX2                     | This leaf function accepts changes made by system software to an EPC page in the running enclave. |

**Instruction Operand Encoding**

| Op/En | EAX          |                         | RBX                       | RCX                                      |
|-------|--------------|-------------------------|---------------------------|------------------------------------------|
| IR    | EACCEPT (In) | Return Error Code (Out) | Address of a SECINFO (In) | Address of the destination EPC page (In) |

**Description**

This leaf function accepts changes to a page in the running enclave by verifying that the security attributes specified in the SECINFO match the security attributes of the page in the EPCM. This instruction leaf can only be executed when inside the enclave.

RBX contains the effective address of a SECINFO structure while RCX contains the effective address of an EPC page. The table below provides additional information on the memory parameter of the EACCEPT leaf function.

**EACCEPT Memory Parameter Semantics**

| SECINFO                              | EPCPAGE (Destination)            |
|--------------------------------------|----------------------------------|
| Read access permitted by Non Enclave | Read access permitted by Enclave |

The instruction faults if any of the following:

**EACCEPT Faulting Conditions**

|                                                                        |                                                                                  |
|------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| The operands are not properly aligned.                                 | RBX does not contain an effective address in an EPC page in the running enclave. |
| The EPC page is locked by another thread.                              | RCX does not contain an effective address of an EPC page in the running enclave. |
| The EPC page is not valid.                                             | Page type is PT_REG and MODIFIED bit is 0.                                       |
| SECINFO contains an invalid request.                                   | Page type is PT_TCS or PT_TRIM and PENDING bit is 0 and MODIFIED bit is 1.       |
| If security attributes of the SECINFO page make the page inaccessible. |                                                                                  |

The error codes are:

**Table 38-54. EACCEPT Return Value in RAX**

| Error Code (see Table 38-4)  | Description                                                             |
|------------------------------|-------------------------------------------------------------------------|
| No Error                     | EACCEPT successful.                                                     |
| SGX_PAGE_ATTRIBUTES_MISMATCH | The attributes of the target EPC page do not match the expected values. |
| SGX_NOT_TRACKED              | The OS did not complete an ETRACK on the target page.                   |

## Concurrency Restrictions

**Table 38-55. Base Concurrency Restrictions of EACCEPT**

| Leaf    | Parameter        | Base Concurrency Restrictions |             |                                    |
|---------|------------------|-------------------------------|-------------|------------------------------------|
|         |                  | Access                        | On Conflict | SGX_CONFLICT VM Exit Qualification |

| IR    | EACCEPTCOPY (In) | Return Error Code (Out) | Address of a SECINFO (In) | Address of the destination EPC page (In) | Address of the source EPC page (In) |

#### Description

This leaf function copies the contents of an existing EPC page into an uninitialized EPC page (created by EAUG). After initialization, the instruction may also modify the access rights associated with the destination EPC page. This instruction leaf can only be executed when inside the enclave.

RBX contains the effective address of a SECINFO structure while RCX and RDX each contain the effective address of an EPC page. The table below provides additional information on the memory parameter of the EACCEPTCOPY leaf function.

### EACCEPTCOPY Memory Parameter Semantics

| SECINFO                              | EPCPAGE (Destination)                  | EPCPAGE (Source)                 |
|--------------------------------------|----------------------------------------|----------------------------------|
| Read access permitted by Non Enclave | Read/Write access permitted by Enclave | Read access permitted by Enclave |

The instruction faults if any of the following:

### EACCEPTCOPY Faulting Conditions

|                                           |                                                                                      |
|-------------------------------------------|--------------------------------------------------------------------------------------|
| The operands are not properly aligned.    | If security attributes of the SECINFO page make the page inaccessible.               |
| The EPC page is locked by another thread. | If security attributes of the source EPC page make the page inaccessible.            |
| The EPC page is not valid.                | RBX does not contain an effective address in an EPC page in the running enclave.     |
| SECINFO contains an invalid request.      | RCX/RDX does not contain an effective address of an EPC page in the running enclave. |

The error codes are:

Table 38-57. EACCEPTCOPY Return Value in RAX

| Error Code (see Table 38-4)  | Description                                                             |
|------------------------------|-------------------------------------------------------------------------|
| No Error                     | EACCEPTCOPY successful.                                                 |
| SGX_PAGE_ATTRIBUTES_MISMATCH | The attributes of the target EPC page do not match the expected values. |

### Instruction Operand Encoding

|       |               |
|-------|---------------|
| Op/En | EAX           |
| IR    | EDECCSSA (In) |

#### Description

This leaf function changes the current SSA frame by decrementing TCS.CSSA for the current enclave thread. If the enclave has enabled CET shadow stacks or indirect branch tracking, then EDECCSSA also changes the current CET state save frame. This instruction leaf can only be executed inside an enclave.

### EDECCSSA Memory Parameter Semantics

|                              |

#### Description

The ENCLU[EENTER] instruction transfers execution to an enclave. At the end of the instruction, the logical processor is executing in enclave mode at the RIP computed as EnclaveBase + TCS.OENTRY. If the target address is not within the CS segment (32-bit) or is not canonical (64-bit), a #GP(0) results.

### EENTER Memory Parameter Semantics

|                |
|----------------|
| TCS            |
| Enclave access |

EENTER is a serializing instruction. The instruction faults if any of the following occurs:

|                                                                                |                                                                                       |
|--------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| Address in RBX is not properly aligned.                                        | Any TCS.FLAGS's must-be-zero bit is not zero.                                         |
| TCS pointed to by RBX is not valid or available or locked.                     | Current 32/64 mode does not match the enclave mode in SECS.ATTRIBUTES.MODE64.         |
| The SECS is in use.                                                            | Either of TCS-specified FS and GS segment is not a subsets of the current DS segment. |
| Any one of DS, ES, CS, SS is not zero.                                         | If XSAVE available, CR4.OSXSAVE = 0, but SECS.ATTRIBUTES.XFRM ≠ 3.                    |
| CR4.OSFXSR ≠ 1.                                                                | If CR4.OSXSAVE = 1, SECS.ATTRIBUTES.XFRM is not a subset of XCRO.                     |
| If SECS.ATTRIBUTES.AEXNOTIFY ≠ TCS.FLAGS.AEXNOTIFY and TCS.FLAGS.DBGOPTIN = 0. |                                                                                       |

The following operations are performed by EENTER:

- RSP and RBP are saved in the current SSA frame on EENTER and are automatically restored on EEXIT or interrupt.
- The AEP contained in RCX is stored into the TCS for use by AEXs.FS and GS (including hidden portions) are saved and new values are constructed using TCS.OFSBASE/GSBASE (32 and 64-bit mode) and TCS.OFLSLIMIT/GSLIMIT (32-bit mode only). The resulting segments must be a subset of the DS segment.
- If CR4.OSXSAVE == 1, XCRO is saved and replaced by SECS.ATTRIBUTES.XFRM. The effect of RFLAGS.TF depends on whether the enclave entry is opt-in or opt-out (see Section 40.1.2):
  - On opt-out entry, TF is saved and cleared (it is restored on EEXIT or AEX). Any attempt to set TF via a POPF instruction while inside the enclave clears TF (see Section 40.2.5).
  - On opt-in entry, a single-step debug exception is pended on the instruction boundary immediately after EENTER (see Section 40.2.2).

- All code breakpoints that do not overlap with ELRANGE are also suppressed. If the entry is an opt-out entry, all code and data breakpoints that overlap with the ELRANGE are suppressed.
- On opt-out entry, a number of performance monitoring counters and behaviors are modified or suppressed (see Section 40.2.3):
  - All performance monitoring activity on the current thread is suppressed except for incrementing and firing of FIXED\_CTR1 and FIXED\_CTR2.
  - PEBS is suppressed.
  - AnyThread counting on other threads is demoted to MyThread mode and IA32\_PERF\_GLOBAL\_STATUS[60] on that thread is set
  - If the opt-out entry on a hardware thread results in suppression of any performance monitoring, then the processor sets IA32\_PERF\_GLOBAL\_STATUS[60] and IA32\_PERF\_GLOBAL\_STATUS[63].

### Concurrency Restrictions

**Table 38-62. Base Concurrency Restrictions of EENTER**

| Leaf   | Parameter    | Base Concurrency Restrictions |             |                                    |
|--------|--------------|-------------------------------|-------------|------------------------------------|

**EEXIT—Exits an Enclave**

| Opcode/<br>Instruction    | Op/En | 64/32<br>bit Mode<br>Support | CPUID<br>Feature<br>Flag | Description                                    |
|---------------------------|-------|------------------------------|--------------------------|------------------------------------------------|
| EAX = 04H<br>ENCLU[EEXIT] | IR    | V/V                          | SGX1                     | This leaf function is used to exit an enclave. |

**Instruction Operand Encoding**

|       |            |                                         |                                  |
|-------|------------|-----------------------------------------|----------------------------------|
| Op/En | EAX        | RBX                                     | RCX                              |
| IR    | EEXIT (In) | Target address outside the enclave (In) | Address of the current AEP (Out) |

**Description**

The ENCLU[EEXIT] instruction exits the currently executing enclave and branches to the location specified in RBX. RCX receives the current AEP. If RBX is not within the CS (32-bit mode) or is not canonical (64-bit mode) a #GP(0) results.

**EEXIT Memory Parameter Semantics**

|                                     |
|-------------------------------------|
| Target Address                      |
| Non-Enclave read and execute access |

If RBX specifies an address that is inside the enclave, the instruction will complete normally. The fetch of the next instruction will occur in non-enclave mode, but will attempt to fetch from inside the enclave. This fetch returns a fixed data pattern.

If secrets are contained in any registers, it is responsibility of enclave software to clear those registers.

If XCR0 was modified on enclave entry, it is restored to the value it had at the time of the most recent EENTER or ERESUME.

If the enclave is opt-out, RFLAGS.TF is loaded from the value previously saved on EENTER.

Code and data breakpoints are unsuppressed.

Performance monitoring counters are unsuppressed.

### Instruction Operand Encoding

| Op/En | EAX          |                         | RBX                          | RCX                            |
|-------|--------------|-------------------------|------------------------------|--------------------------------|
| IR    | EGETKEY (In) | Return error code (Out) | Address to a KEYREQUEST (In) | Address of the OUTPUTDATA (In) |

#### Description

The ENCLU[EGETKEY] instruction returns a 128-bit secret key from the processor specific key hierarchy. The register RBX contains the effective address of a KEYREQUEST structure, which the instruction interprets to determine the key being requested. The Requesting Keys section below provides a description of the keys that can be requested. The RCX register contains the effective address where the key will be returned. Both the addresses in RBX & RCX should be locations inside the enclave.

EGETKEY derives keys using a processor unique value to create a specific key based on a number of possible inputs. This instruction leaf can only be executed inside an enclave.

### EGETKEY Memory Parameter Semantics

| KEYREQUEST          | OUTPUTDATA           |
|---------------------|----------------------|
| Enclave read access | Enclave write access |

After validating the operands, the instruction determines which key is to be produced and performs the following actions:

- The instruction assembles the derivation data for the key based on the Table 38-66.
- Computes derived key using the derivation data and package specific value.
- Outputs the calculated key to the address in RCX.

The instruction fails with #GP(0) if the operands are not properly aligned. Successful completion of the instruction will clear RFLAGS.{ZF, CF, AF, OF, SF, PF}. The instruction returns an error code if the user tries to request a key based on an invalid CPUSVN or ISVSVN (when the user request is accepted, see the table below), requests a key for which it has not been granted the attribute to request, or requests a key that is not supported by the hardware. These checks may be performed in any order. Thus, an indication by error number of one cause (for example, invalid attribute) does not imply that there are not also other errors. Different processors may thus give different error numbers for the same Enclave. The correctness of software should not rely on the order resulting from the checks documented in this section. In such cases the ZF flag is set and the corresponding error bit (SGX\_IN-VALID\_SVN, SGX\_INVALID\_ATTRIBUTE, SGX\_INVALID\_KEYNAME) is set in RAX and the data at the address specified by RCX is unmodified.

#### Requesting Keys

The KEYREQUEST structure (see Section 35.18.1) identifies the key to be provided. The Keyrequest.KeyName field identifies which type of key is requested.

#### Deriving Keys

Key derivation is based on a combination of the enclave specific values (see Table 38-66) and a processor key. Depending on the key being requested a field may either be included by definition or the value may be included from the KeyRequest. A “yes” in Table 38-66 indicates the value for the field is included from its default location, identified in the source row, and a “request” indicates the values for the field is included from its corresponding KeyRequest field.

**Table 38-66. Key Derivation**

|                   | Key Name               | Attributes                                                                      | Owner Epoch        | CPU SVN                                                         | ISV SVN                           | ISV PRODID         | ISVEXT PRODID  | ISVFAM ILYID  | MRENCLAVE      | MRSIGNER        | CONFIG ID | CONFIGS VN | RAND    |

Keys that permit the specification of a CPU or ISV's code's, or enclave configuration's SVNs have additional requirements. The caller may not request a key for an SVN beyond the current CPU, ISV or enclave configuration's SVN, respectively.

Several keys are access controlled. Access to the Provisioning Key and Provisioning Seal key requires the enclave's ATTRIBUTES.PROVISIONKEY be set. The EINITTOKEN Key requires ATTRIBUTES.EINITTOKEN\_KEY be set and SECS.MRSIGNER equal IA32\_SGXLEPUBKEYHASH.

Some keys are derived based on a hardcode PKCS padding constant (352 byte string):

```
HARDCODED_PKCS1_5_PADDING[15:0] := 0100H;
HARDCODED_PKCS1_5_PADDING[2655:16] := SignExtend330Byte(-1); // 330 bytes of 0FFH
HARDCODED_PKCS1_5_PADDING[2815:2656] := 2004000501020403650148866009060D30313000H;
```

The error codes are:

**Table 38-67. EGETKEY Return Value in RAX**

| Error Code (see Table 38-4) | Value | Description                                                                                       |
|-----------------------------|-------|---------------------------------------------------------------------------------------------------|
| No Error                    | 0     | EGETKEY successful.                                                                               |
| SGX_INVALID_ATTRIBUTE       |       | The KEYREQUEST contains a KEYNAME for which the enclave is not authorized.                        |
| SGX_INVALID_CPUSVN          |       | If KEYREQUEST.CPUSVN is an unsupported platforms CPUSVN value.                                    |
| SGX_INVALID_ISVSVN          |       | If KEYREQUEST software SVN (ISVSVN or CONFIGSVN) is greater than the enclave's corresponding SVN. |
| SGX_INVALID_KEYNAME         |       | If KEYREQUEST.KEYNAME is an unsupported value.                                                    |

### Concurrency Restrictions

**Table 38-68. Base Concurrency Restrictions of EGETKEY**

| Leaf    | Parameter           | Base Concurrency Restrictions |             |                                    |
|---------|---------------------|-------------------------------|-------------|------------------------------------|
|         |                     | Access                        | On Conflict | SGX_CONFLICT VM Exit Qualification |
| EGETKEY | KEYREQUEST [DS:RBX] | Concurrent                    |             |                                    |
|         | OUTPUTDATA [DS:RCX] | Concurrent                    |             |                                    |

**Table 38-69. Additional Concurrency Restrictions of EGETKEY**

| Leaf    | Parameter              | Additional Concurrency Restrictions                |             |                          |             |                     |             |
|---------|------------------------|----------------------------------------------------|-------------|--------------------------|-------------|---------------------|-------------|

|-------|-------------|---------------------------|------------------------------------------|
| Op/En | EAX         | RBX                       | RCX                                      |
| IR    | EMODPE (In) | Address of a SECINFO (In) | Address of the destination EPC page (In) |

#### Description

This leaf function extends the access rights associated with an existing EPC page in the running enclave. THE RWX bits of the SECINFO parameter are treated as a permissions mask; supplying a value that does not extend the page permissions will have no effect. This instruction leaf can only be executed when inside the enclave.

RBX contains the effective address of a SECINFO structure while RCX contains the effective address of an EPC page. The table below provides additional information on the memory parameter of the EMODPE leaf function.

### EMODPE Memory Parameter Semantics

| SECINFO                              | EPCPAGE                          |
|--------------------------------------|----------------------------------|
| Read access permitted by Non Enclave | Read access permitted by Enclave |

The instruction faults if any of the following:

### EMODPE Faulting Conditions

|                                           |                                                                                  |
|-------------------------------------------|----------------------------------------------------------------------------------|
| The operands are not properly aligned.    | If security attributes of the SECINFO page make the page inaccessible.           |
| The EPC page is locked by another thread. | RBX does not contain an effective address in an EPC page in the running enclave. |
| The EPC page is not valid.                | RCX does not contain an effective address of an EPC page in the running enclave. |
| SECINFO contains an invalid request.      |                                                                                  |

#### Concurrency Restrictions

|-------|--------------|-------------------------------|-------------------------------|-----------------------------------------------------------------|
| IR    | EREPORT (In) | Address of TARGETINFO<br>(In) | Address of REPORTDATA<br>(In) | Address where the REPORT is<br>written to in an OUTPUTDATA (In) |

**Description**

This leaf function creates a cryptographic REPORT that describes the contents of the enclave. This instruction leaf can only be executed when inside the enclave. The cryptographic report can be used by other enclaves to determine that the enclave is running on the same platform.

RBX contains the effective address of the MRENCLAVE value of the enclave that will authenticate the REPORT output, using the REPORT key delivered by EGETKEY command for that enclave. RCX contains the effective address of a 64-byte REPORTDATA structure, which allows the caller of the instruction to associate data with the enclave from which the instruction is called. RDX contains the address where the REPORT will be output by the instruction.

**EREPORT Memory Parameter Semantics**

| TARGETINFO             | REPORTDATA             | OUTPUTDATA                   |
|------------------------|------------------------|------------------------------|
| Read access by Enclave | Read access by Enclave | Read/Write access by Enclave |

This instruction leaf perform the following:

1. Validate the 3 operands (RBX, RCX, RDX) are inside the enclave.
2. Compute a report key for the target enclave, as indicated by the value located in RBX(TARGETINFO).
3. Assemble the enclave SECS data to complete the REPORT structure (including the data provided using the RCX (REPORTDATA) operand).
4. Computes a cryptographic hash over REPORT structure.
5. Add the computed hash to the REPORT structure.
6. Output the completed REPORT structure to the address in RDX (OUTPUTDATA).

The instruction fails if the operands are not properly aligned.

CR\_REPORT\_KEYID, used to provide key wearout protection, is populated with a statistically unique value on boot of the platform by a trusted entity within the SGX TCB.

The instruction faults if any of the following:

**EREPORT Faulting Conditions**

#### Description

The ENCLU[ERESUME] instruction resumes execution of an enclave that was interrupted due to an exception or interrupt, using the machine state previously stored in the SSA.

### ERESUME Memory Parameter Semantics

|                           |
|---------------------------|
| TCS                       |
| Enclave read/write access |

The instruction faults if any of the following occurs:

|                                                            |                                                                                                 |
|------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| Address in RBX is not properly aligned.                    | Any TCS.FLAGS's must-be-zero bit is not zero.                                                   |
| TCS pointed to by RBX is not valid or available or locked. | Current 32/64 mode does not match the enclave mode in SECS.ATTRIBUTES.MODE64.                   |
| The SECS is in use by another enclave.                     | Either of TCS-specified FS and GS segment is not a subset of the current DS segment.            |
| Any one of DS, ES, CS, SS is not zero.                     | If XSAVE available, CR4.OSXSAVE = 0, but SECS.ATTRIBUTES.XFRM ≠ 3.                              |
| CR4.OSFXSR ≠ 1.                                            | If CR4.OSXSAVE = 1, SECS.ATTRIBUTES.XFRM is not a subset of XCR0.                               |
| Offsets 520-535 of the XSAVE area not 0.                   | The bit vector stored at offset 512 of the XSAVE area must be a subset of SECS.ATTRIBUTES.XFRM. |
| The SSA frame is not valid or in use.                      | If SECS.ATTRIBUTES.AEXNOTIFY ≠ TCS.FLAGS.AEXNOTIFY and TCS.FLAGS.DBGOPTIN = 0.                  |

The following operations are performed by ERESUME:

- RSP and RBP are saved in the current SSA frame on EENTER and are automatically restored on EEXIT or an asynchronous exit due to any Interrupt event.
- The AEP contained in RCX is stored into the TCS for use by AEXs.FS and GS (including hidden portions) are saved and new values are constructed using TCS.OFSBASE/GSBASE (32 and 64-bit mode) and TCS.OFSLIMIT/GSLIMIT (32-bit mode only). The resulting segments must be a subset of the DS segment.
- If CR4.OSXSAVE == 1, XCR0 is saved and replaced by SECS.ATTRIBUTES.XFRM. The effect of RFLAGS.TF depends on whether the enclave entry is opt-in or opt-out (see Section 40.1.2):
  - On opt-out entry, TF is saved and cleared (it is restored on EEXIT or AEX). Any attempt to set TF via a POPF instruction while inside the enclave clears TF (see Section 40.2.5).
  - On opt-in entry, a single-step debug exception is pended on the instruction boundary immediately after EENTER (see Section 40.2.3).
- All code breakpoints that do not overlap with ELRANGE are also suppressed. If the entry is an opt-out entry, all code and data breakpoints that overlap with the ELRANGE are suppressed.

- On opt-out entry, a number of performance monitoring counters and behaviors are modified or suppressed (see Section 40.2.3):
  - All performance monitoring activity on the current thread is suppressed except for incrementing and firing of FIXED\_CTR1 and FIXED\_CTR2.
  - PEBS is suppressed.
  - AnyThread counting on other threads is demoted to MyThread mode and IA32\_PERF\_GLOBAL\_STATUS[60] on that thread is set.
  - If the opt-out entry on a hardware thread results in suppression of any performance monitoring, then the processor sets IA32\_PERF\_GLOBAL\_STATUS[60] and IA32\_PERF\_GLOBAL\_STATUS[63].

### Concurrency Restrictions

**Table 38-74. Base Concurrency Restrictions of ERESUME**

| Leaf    | Parameter    | Base Concurrency Restrictions |             |                                    |
|---------|--------------|-------------------------------|-------------|------------------------------------|
|         |              | Access                        | On Conflict | SGX_CONFLICT VM Exit Qualification |
| ERESUME | TCS [DS:RBX] | Shared                        | #GP         |                                    |

**Table 38-75. Additional Concurrency Restrictions of ERESUME**

| Leaf    | Parameter    | Additional Concurrency Restrictions             |             |                          |             |                     |             |
|---------|--------------|-------------------------------------------------|-------------|--------------------------|-------------|---------------------|-------------|
|         |              | vs. EACCEPT, EACCEPTCOPY, EMODPE, EMODPR, EMODT |             | vs. EADD, EEXTEND, EINIT |             | vs. ETRACK, ETRACKC |             |
|         |              | Access                                          | On Conflict | Access                   | On Conflict | Access              | On Conflict |
| ERESUME | TCS [DS:RBX] | Concurrent                                      |             | Concurrent               |             | Concurrent          |             |

### Operation

If DS:RBX does not point to a valid TCS.  
If one or more pages of the current SSA frame are not readable/writable, or do not resolve to a valid PT\_REG EPC page.

## 38.5 INTEL® SGX VIRTUALIZATION LEAF FUNCTION REFERENCE

Leaf functions available with the ENCLV instruction mnemonic are covered in this section. In general, each instruction leaf requires EAX to specify the leaf function index and/or additional implicit registers specifying leaf-specific input parameters. An instruction operand encoding table provides details of each implicit register usage and associated input/output semantics.

In many cases, an input parameter specifies an effective address associated with a memory object inside or outside the EPC, the memory addressing semantics of these memory objects are also summarized in a separate table.

**EDECVIRTCHILD—Decrement VIRTCHILDCNT in SECS**

| Opcode/<br>Instruction            | Op/En | 64/32<br>bit Mode<br>Support | CPUID<br>Feature<br>Flag | Description                                                |
|-----------------------------------|-------|------------------------------|--------------------------|------------------------------------------------------------|
| EAX = OOH<br>ENCLV[EDECVIRTCHILD] | IR    | V/V                          | EAX[5]                   | This leaf function decrements the SECS VIRTCHILDCNT field. |

**Instruction Operand Encoding**

| Op/En | EAX                |                         | RBX                             | RCX                          |
|-------|--------------------|-------------------------|---------------------------------|------------------------------|
| IR    | EDECVIRTCHILD (In) | Return error code (Out) | Address of an enclave page (In) | Address of an SECS page (In) |

**Description**

This instruction decrements the SECS VIRTCHILDCNT field. This instruction can only be executed when current privilege level is 0.

The content of RCX is an effective address of an EPC page. The DS segment is used to create linear address. Segment override is not supported.

**EDECVIRTCHILD Memory Parameter Semantics**

| EPPAGE                                     | SECS                             |
|--------------------------------------------|----------------------------------|
| Read/Write access permitted by Non Enclave | Read access permitted by Enclave |

The instruction faults if any of the following:

**EDECVIRTCHILD Faulting Conditions**

|                                                                                |                                                                               |
|--------------------------------------------------------------------------------|-------------------------------------------------------------------------------|
| A memory operand effective address is outside the DS segment limit (32b mode). | A page fault occurs in accessing memory operands.                             |
| DS segment is unusable (32b mode).                                             | RBX does not refer to an enclave page (REG, TCS, TRIM, SECS).                 |
| A memory address is in a non-canonical form (64b mode).                        | RCX does not refer to an SECS page.                                           |
| A memory operand is not properly aligned.                                      | RBX does not refer to an enclave page associated with SECS referenced in RCX. |

## ESETCONTEXT—Set the ENCLAVECONTEXT Field in SECS

| Opcode/<br>Instruction          | Op/En | 64/32<br>bit Mode<br>Support | CPUID<br>Feature<br>Flag | Description                                               |
|---------------------------------|-------|------------------------------|--------------------------|-----------------------------------------------------------|
| EAX = 02H<br>ENCLV[ESETCONTEXT] | IR    | V/V                          | EAX[5]                   | This leaf function sets the ENCLAVECONTEXT field in SECS. |

### Instruction Operand Encoding

| Op/En | EAX              |                         | RCX                                          | RDX                    |
|-------|------------------|-------------------------|----------------------------------------------|------------------------|
| IR    | ESETCONTEXT (In) | Return error code (Out) | Address of the destination EPC page (In, EA) | Context Value (In, EA) |

#### Description

The ESETCONTEXT leaf overwrites the ENCLAVECONTEXT field in the SECS. ECREATE and ELD of an SECS set the ENCLAVECONTEXT field in the SECS to the address of the SECS (for access later in ERDINFO). The ESETCONTEXT instruction allows a VMM to overwrite the default context value if necessary, for example, if the VMM is emulating ECREATE or ELD on behalf of the guest.

The content of RCX is an effective address of the SECS page to be updated, RDX contains the address pointing to the value to be stored in the SECS. The DS segment is used to create linear address. Segment override is not supported.

The instruction fails if:

- The operand is not properly aligned.
- RCX does not refer to an SECS page.

### ESETCONTEXT Memory Parameter Semantics

| EPCPAGE                          | CONTEXT                                    |
|----------------------------------|--------------------------------------------|
| Read access permitted by Enclave | Read/Write access permitted by Non Enclave |

The instruction faults if any of the following:

### ESETCONTEXT Faulting Conditions

|                                                                                |                                                   |

CF, PF, AF, OF, and SF are cleared.

#### **Protected Mode Exceptions**

|                 |                                                                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| #GP(0)          | If a memory operand effective address is outside the DS segment limit.<br>If DS segment is unusable.<br>If a memory operand is not properly aligned. |
| #PF(error code) | If a page fault occurs in accessing memory operands.                                                                                                 |

#### **64-Bit Mode Exceptions**

|                 |                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------|
| #GP(0)          | If a memory address is in a non-canonical form.<br>If a memory operand is not properly aligned. |
| #PF(error code) | If a page fault occurs in accessing memory operands.                                            |

**CHAPTER 39****INTEL® SGX INTERACTIONS WITH IA32 AND INTEL® 64 ARCHITECTURE**

Intel® SGX provides Intel® Architecture with a collection of enclave instructions for creating protected execution environments on processors supporting IA32 and Intel® 64 architectures. These Intel SGX instructions are designed to work with legacy software and the various IA32 and Intel 64 modes of operation.

## **39.1 INTEL® SGX AVAILABILITY IN VARIOUS PROCESSOR MODES**

The Intel SGX extensions (see Table 34-1) are available only when the processor is executing in protected mode of operation. Additionally, the extensions are not available in System Management Mode (SMM) of operation or in Virtual 8086 (VM86) mode of operation. Finally, all leaf functions of ENCLU and ENCLS require CR0.PG enabled.

The exact details of exceptions resulting from illegal modes and their priority are listed in the reference pages of ENCLS and ENCLU.

## **39.2 IA32\_FEATURE\_CONTROL**

IA32\_FEATURE\_CONTROL MSR provides two new bits related to two aspects of Intel SGX: using the instruction extensions and launch control configuration.

### **39.2.1 Availability of Intel SGX**

IA32\_FEATURE\_CONTROL[bit 18] allows BIOS to control the availability of Intel SGX extensions. For Intel SGX extensions to be available on a logical processor, bit 18 in the IA32\_FEATURE\_CONTROL MSR on that logical processor must be set, and IA32\_FEATURE\_CONTROL MSR on that logical processor must be locked (bit 0 must be set). See Section 34.7.1 for additional details. OS is expected to examine the value of bit 18 prior to enabling Intel SGX on the thread, as the settings of bit 18 is not reflected by CPUID.

### **39.2.2 Intel SGX Launch Control Configuration**

The IA32\_SGXLEPUBKEYHASHn MSRs used to configure authorized launch enclaves' MRSIGNER digest value. They are present on logical processors that support the collection of SGX1 leaf functions (i.e., CPUID.(EAX=12H, ECX=00H):EAX[0] = 1) and that CPUID.(EAX=07H, ECX=00H):ECX[30] = 1. IA32\_FEATURE\_CONTROL[bit 17] allows to BIOS to enable write access to these MSRs. If IA32\_FEATURE\_CONTROL.LE\_WR (bit 17) is set to 1 and IA32\_FEATURE\_CONTROL is locked on that logical processor, IA32\_SGXLEPUBKEYHASH MSRs on that logical processor are writeable. If this bit 17 is not set or IA32\_FEATURE\_CONTROL is not locked, IA32\_SGXLEPUBKEYHASH MSRs are read only. See Section 36.1.4 for additional details.

## **39.3 INTERACTIONS WITH SEGMENTATION**

### **39.3.1 Scope of Interaction**

Intel SGX extensions are available only when the processor is executing in a protected mode operation (see Section 39.1 for Intel SGX availability in various processor modes). Enclaves abide by all the segmentation policies set up by the OS, but they can be more restrictive than the OS.

Intel SGX interacts with segmentation at two levels:

- The Intel SGX instruction (see the enclave instruction in Table 34-1).

- While executing inside an enclave (legacy instructions and enclave instructions permitted inside an enclave).

### 39.3.2 Interactions of Intel® SGX Instructions with Segment, Operand, and Addressing Prefixes

All the memory operands used by the Intel SGX instructions are interpreted as offsets within the data segment (DS). The segment-override prefix on Intel SGX instructions is ignored.

Operand size is fixed for each enclave instruction. The operand-size prefix is reserved, and results in a #UD exception if used.

All address sizes are determined by the operating mode of the processor. The address-size prefix is ignored. This implies that while operating in 64-bit mode of operation, the address size is always 64 bits, and while operating in 32-bit mode of operation, the address size is always 32 bits. Additionally, when operating in 16-bit addressing, memory operands used by enclave instructions use 32 bit addressing; the value of CS.D is ignored.

### 39.3.3 Interaction of Intel® SGX Instructions with Segmentation

All leaf functions of ENCLU and ENCLS instructions require that the DS segment be usable, and be an expand-up segment. Failing this check results in generation of a #GP(0) exception.

The Intel SGX leaf functions used for entering the enclave (ENCLU[EENTER] and ENCLU[ERESUME]) operate as follows:

- All usable segment registers except for FS and GS have a zero base.
- The contents of the FS/GS segment registers (including the hidden portion) is saved in the processor.
- New FS and GS values compatible with enclave security are loaded from the TCS
- The linear ranges and access rights available under the newly-loaded FS and GS must abide to OS policies by ensuring they are subsets of the linear-address range and access rights available for the DS segment.
- The CS segment mode (64-bit, compatible, or 32 bit modes) must be consistent with the segment mode for which the enclave was created, as indicated by the SECS.ATTRIBUTES.MODE64 bit, and that the CPL of the logical processor is 3

An exit from the enclave either via ENCLU[EEXIT] or via an AEX restores the saved values of FS/GS segment registers.

### 39.3.4 Interactions of Enclave Execution with Segmentation

During the course of execution, enclave code abides by all segmentation policies as dictated by IA32 and Intel 64 Architectures, and generates appropriate exceptions on violations.

Additionally, any attempt by software executing inside an enclave to modify the processor's segmentation state (e.g., via MOV seg register, POP seg register, LDS, far jump, etc; excluding WRFSBASE/WRGSBASE) results in the generation of a #UD. See Section 36.6.1 for more information.

Upon enclave entry via the EENTER leaf function, FS is loaded from the (TCS.OFSBASE + SECS.BASEADDR) and TCS.FSLIMIT fields and GS is loaded from the (TCS.OGSBASE + SECS.BASEADDR) and TCS.GSLIMIT fields.

Execution of WRFSBASE and WRGSBASE from inside a 64-bit enclave is allowed. The processor will save the new values into the current SSA frame on an asynchronous exit (AEX) and restore them back on enclave entry via ENCLU[ERESUME] instruction.

## 39.4 INTERACTIONS WITH PAGING

Intel SGX instructions are available only when the processor is executing in a protected mode of operation. Additionally, all Intel SGX leaf functions except for EDBG RD and EDBG WR are available only if paging is enabled. Any attempt to execute these leaf functions with paging disabled results in an invalid-opcode exception (#UD). As with

segmentation, enclaves abide by all the paging policies set up by the OS, but they can be more restrictive than the OS.

All the memory operands passed into Intel SGX instructions are interpreted as offsets within the DS segment, and the linear addresses generated by combining these offsets with DS segment register are subject to paging-based access control if paging is enabled at the time of the execution of the leaf function.

Since the ENCLU[EENTER] and ENCLU[ERESUME] can only be executed when paging is enabled, and since paging cannot be disabled by software running inside an enclave (recall that enclaves always run with CPL = 3), enclave execution is always subject to paging-based access control. The Intel SGX access control itself is implemented as an extension to the existing paging modes. See Section 35.5 for details.

Execution of Intel SGX instructions may set accessed and dirty flags on accesses to EPC pages that do not fault even if the instruction later causes a fault for some other reason.

## 39.5 INTERACTIONS WITH VMX

Intel SGX functionality (including SGX1 and SGX2) can be made available to software running in either VMX root operation or VMX non-root operation, as long as the processor is using a legal mode of operation (see Section 39.1).

A VMM has the flexibility to configure a VMCS to permit a guest to use any subset of the ENCLS leaf functions. Availability of the ENCLU leaf functions in VMX non-root operation has the same requirement as ENCLU leaf functions outside of a virtualized environment.

Details of the VMCS control to allow VMM to configure support of Intel SGX in VMX non-root operation is described in Section 39.5.1

### 39.5.1 VMM Controls to Configure Guest Support of Intel® SGX

Intel SGX capabilities are primarily exposed to the software via the CPUID instruction. VMMs can virtualize CPUID instruction to expose/hide this capability to/from guests.

Some of Intel SGX resources are exposed/controlled via model-specific registers (see Section 34.7). VMMs can virtualize these MSRs for the guests using the MSR bitmaps referenced by pointers in the VMCS.

The VMM can partition the Enclave Page Cache, and assign various partitions to (a subset of) its guests via the usual memory-virtualization techniques such as paging or the extended page table mechanism (EPT).

The VMM can set the “enable ENCLS exiting” VM-execution controls to cause a VM exit when the ENCLS instruction is executed in VMX non-root operation. If the “enable ENCLS exiting” control is 0, all of the ENCLS leaf functions are permitted in VMX non-root operation. If the “enable ENCLS exiting” control is 1, execution of ENCLS leaf functions in VMX non-root operation is governed by consulting the bits in a new 64-bit VM-execution control field called the ENCLS-exiting bitmap (Each bit in the bitmap corresponds to an ENCLS leaf function with an EAX value that is identical to the bit’s position). When bits in the “ENCLS-exiting bitmap” are set, attempts to execute the corresponding ENCLS leaf functions in VMX non-root operation causes VM exits. The checking for these VM exits occurs immediately after checking that CPL = 0.

### 39.5.2 Interactions with the Extended Page Table Mechanism (EPT)

Intel SGX instructions are fully compatible with the extended page-table mechanism (EPT; see Section 29.3).

All the memory operands passed into Intel SGX instructions are interpreted as offsets within the DS segment, and the linear addresses generated by combining these offsets with DS segment register are subject to paging and EPT. As with paging, enclaves abide by all the policies set up by the VMM.

The Intel SGX access control itself is implemented as an extension to paging and EPT, and may be more restrictive. See Section 39.4 for details of this extension.

An execution of an Intel SGX instruction may set accessed and dirty flags for EPT (when enabled; see Section 29.3.5) on accesses to EPC pages that do not fault or cause VM exits even if the instruction later causes a fault or VM exit for some other reason.

### 39.5.3 Interactions with APIC Virtualization

This section applies to Intel SGX in VMX non-root operation when the “virtualize APIC accesses” VM-execution control is 1.

A memory access by an enclave instruction that implicitly uses a cached physical address is never checked for overlap with the APIC-access page. Such accesses never cause APIC-access VM exits and are never redirected to the virtual-APIC page. Implicit memory accesses can only be made to the SECS, the TCS, or the SSA of an enclave (see Section 35.5.3.2).

An explicit Enclave Access (a linear memory access which is either from within an enclave into its ELRANGE, or an access by an Intel SGX instruction that is expected to be in the EPC) that overlaps with the APIC-access page causes a #PF exception (APIC page is expected to be outside of EPC).

Non-Enclave accesses made either by an Intel SGX instruction or by a logical processor inside an enclave to an address that without SGX would have caused redirection to the virtual-APIC page instead cause an APIC-access VM exit.

Other than implicit accesses made by Intel SGX instructions, guest-physical and physical accesses are not considered “enclave accesses”; consequently, such accesses result in undefined behavior if these accesses eventually reach EPC. This applies to any non-enclave physical accesses.

While a logical processor is executing inside an enclave, an attempt to execute an instruction outside of ELRANGE results in a #GP(0), even if the linear address would translate to a physical address that overlaps the APIC-access page.

### 39.5.4 Interactions with VT and SGX concurrency

In some cases, a VMM is required to handle conflicts between its own operation and a guest operation on EPC pages that are present in both guest and VMM address space. These conflict would otherwise cause the guest to experience an unexpected behavior (vs. running directly on the h/w). These conflict cases are:

- ETRACK/ETRACKC failure due to Entry Epoch Object Lock conflict or reference tracking check failure.
- EPC Page Resource conflict.

A new exit reason is defined for all those cases: SGX\_CONFLICT (value 71). The VMCS exit qualification field details the specific case as follows:

**Table 39-1. SGX Conflict Exit Qualification**

| Bits  | Size (bits) | Name     | Description                                                                                                                                                                                                                                                                                                                                             |
|-------|-------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0  | 16          | Code     | Exit qualification code. The following values are defined:<br>0: TRACKING_RESOURCE_CONFLICT<br>1: TRACKING_REFERENCE_CONFLICT<br>2: EPC_PAGE_CONFLICT_EXCEPTION<br>3: EPC_PAGE_CONFLICT_ERROR<br>Other: Reserved                                                                                                                                        |
| 31:16 | 16          | Error    | Error code. Applicable only if the exit qualification code is EPC_PAGE_CONFLICT_ERROR; contains the error code that would be returned in RAX if the instruction was executed on bare metal platform or if the ENABLE_EPC_VIRTUALIZATION_EXTENSIONS bit in the secondary processor control field is not set. In other cases this field is reserved as 0. |
| 63:32 | 32          | Reserved | Always 0.                                                                                                                                                                                                                                                                                                                                               |

This SGX\_CONFLICT exiting behavior is controlled by a VM execution control called ENABLE\_EPC\_VIRTUALIZATION\_EXTENSIONS (bit 29 of the secondary processor control field).

Details for various SGX\_CONFLICT VMEXIT cases are provided in the following sections.

### 39.5.5 Virtual Child Tracking

SGX oversubscription support adds the ability to associate virtual children with each enclave using the ENCLV[EINCVIRTCHILD] and ENCLV[EDECVIRTCHILD] instructions. The VMM enables checking of the virtual child count by EREMOVE and EWB in guests with a new VM execution control called ENABLE\_EPC\_VIRTUALIZATION\_EXTENSIONS.

When in VMX non-root operation and the ENABLE\_EPC\_VIRTUALIZATION\_EXTENSIONS control enabled, the following instructions change their behavior:

- EWB and EREMOVE return the SGX\_CHILD\_PRESENT error code if any virtual or physical children are associated with the enclave.
- ERDINFO set STATUS.CHILDPRESENT if any virtual or physical children are associated with the enclave.

### 39.5.6 Handling EPCM Entry Lock Conflicts

When performing paging within a VMM, it is possible for a contention on the EPC page to happen in the following case:

- The VMM performs an ELDB/ELDU/ELDBC/ELDUC of an enclave page, and the guest attempts to perform some SGX instruction (e.g., EREMOVE) where the same SECS parent page is required.

A similar conflict may occur if the VMM uses EINCVIRTCHILD or EDECVIRTCHILD pointing to an SECS page. In all other cases where a SGX instruction executed by the VMM the applicable EPC page should not be mapped to the guest, thus no resource conflict occurs.

This conflicting situation can cause the guest's instruction to fail and cause guest instability. To help the VMM manage such conflicts, the SGX VMM paging extensions introduce a new VM-Exit that will be triggered whenever the guest encounters a resource conflict.

The exit reason is SGX\_CONFLICT. The exit qualification field is used to distinguish the two kinds of resource conflicts:

- A value of EPCM\_RESOURCE\_CONFLICT\_EXCEPTION (2) in the exit qualification code field indicates that a resource conflict occurred that would result in a #GP. In that case, the exit qualification error field is set to zero.
- A value of EPC\_PAGE\_CONFLICT\_ERROR (3) in the exit qualification code field indicates that a resource conflict occurred that would result in an error code being returned in RAX. In that case, the exit qualification error field is set to SGX\_EPC\_PAGE\_CONFLICT.

The Guest Linear Address and Guest Physical Address fields are set to the guest linear and guest physical addresses respectively of the EPC page on which the conflict occurred. The VMM may determine which instruction induced the exit by reading RAX. The exit also populates the VM-exit instruction length field.

The VMM can determine whether the conflict may be due to its own operation, e.g., by setting a per-enclave busy indicator before executing ELD\*, and clearing it afterwards. In that case, the VMM can handle an SGX Conflict (EPCM\_PAGE\_CONFLICT\_\*) exit by resuming guest execution at the same instruction, allowing the guest to re-execute the instruction. The VMM may also take steps to throttle its own paging thread to reduce contention with the guest.

If the VMM determines that the conflict is not due to its own operation, it may inject a #GP (in case of EPC\_PAGE\_CONFLICT\_EXCEPTION), or emulate an error code as the guest instruction would return (in case of EPC\_PAGE\_CONFLICT\_ERROR) by setting ZF and copying the error value provided in the exit qualification to guest RAX.

To gracefully handle resource contention on the VMM side, the VMM should use the new ELDBC and ELDUC instructions. These are similar to ELDB and ELDU respectively, except that on EPC resource contention they return an SGX\_EPC\_PAGE\_CONFLICT error instead of issuing a #GP. In case of an error, the VMM can retry the instruction, possibly throttling the guest to assure progress.

When using EDECVIRTCHILD and EINCVIRTCHILD, the VMM should preferably point to the enclave child page, not to the SECS page, avoiding resource conflict on the SECS. If the VMM chooses to point to the SECS page, it should handle conflicts in the same way as handling the ELD\* case.

### 39.5.7 Context Tracking

The ENCLAVECONTEXT field in the SECS is available for use by the VMM to track context information associated with that enclave, such as the GPA of the SECS in the context of the appropriate guest. This field is initialized by the successful execution of ECREATE and ELD of an SECS page. The value stored in the ENCLAVECONTEXT field will be the translation of the target page address produced by paging (GPA in VMMs that have EPTs turned on). VMMs may override this default value by calling the ENCLV[ESETCONTEXT] instruction, which allows the VMM to store an arbitrary 64-bit value in the ENCLAVECONTEXT field. The VMM may later access the ENCLAVECONTEXT field by calling ENCLS[ERDINFO] on any member page of the enclave, including the SECS.

For nested virtualization cases, the lowest level VMM can make SGX oversubscription instructions higher level guest VMMs. In that case the lower level VMM can simply inject #GP to higher level VMMs when attempting to execute these instructions.

However, if VMMs expose SGX oversubscription instructions to higher level VMMs, then VMMs have to use ENCLV[ESETCONTEXT] instruction to properly manage the ENCLAVECONTEXT field of SECS during paging operations. That may involve emulating ECREATE, ELD, ESETCONTEXT, and ERDINFO instructions apart from managing ENCLAVECONTEXT values.

## 39.6 INTEL® SGX INTERACTIONS WITH ARCHITECTURALLY-VISIBLE EVENTS

All architecturally visible events (exceptions, interrupts, SMI, NMI, INIT, VM exit) can be detected while inside an enclave and will cause an asynchronous enclave exit if they are not blocked. Additionally, INT3, and the SignalTX-TMsg[SENTER] (i.e., GETSEC[SENTER]'s rendezvous event message) events also cause asynchronous enclave exits. Note that SignalTX-TMsg[SEXIT] (i.e., GETSEC[SEXIT]'s teardown message) does not cause an AEX.

On an AEX, information about the event causing the AEX is stored in the SSA (see Section 37.4 for details of AEX). The information stored in the SSA only describes the first event that triggered the AEX. If parsing/delivery of the first event results in detection of further events (e.g., VM exit, double fault, etc.), then the event information in the SSA is not updated to reflect these subsequently detected events.

## 39.7 INTERACTIONS WITH THE PROCESSOR EXTENDED STATE AND MISCELLANEOUS STATE

### 39.7.1 Requirements and Architecture Overview

Processor extended states are the ISA features that are enabled by the settings of CR4.OSXSAVE and the XCR0 register. Processor extended states are normally saved/restored by software via XSAVE/XRSTOR instructions.

Details of discovery of processor extended states and management of these states are described in CHAPTER 13 of Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A.

Additionally, the following requirements apply to Intel SGX:

- On an AEX, the Intel SGX architecture must protect the processor extended state and miscellaneous state by saving them in the enclave's state-save area (SSA), and clear the secrets from the processor extended state that is used by an enclave.
- Intel SGX architecture must verify that the SSA frame size is large enough to contain all the processor extended states and miscellaneous state used by the enclave.
- Intel SGX architecture must ensure that enclaves can only use processor extended state that is enabled by system software in XCR0.
- Enclave software should be able to discover only those processor extended state and miscellaneous state for which such protection is enabled.
- The processor extended states that are enabled inside the enclave must be approved by the enclave developer:
  - Certain processor extended state (e.g., Memory Protection Extensions, see Appendix E, "Intel® Memory Protection Extensions" of the Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1)

modify the behavior of the legacy ISA software. If such features are enabled for enclaves that do not understand those features, then such a configuration could lead to a compromise of the enclave's security.

- The processor extended states that are enabled inside the enclave must form an integral part of the enclave's identity. This requirement has two implications:
  - Service providers may decide to assign different trust level to the same enclave depending on the ISA features the enclave is using.

To meet these requirements, the Intel SGX architecture defines a sub-field called X-Feature Request Mask (XFRM) in the ATTRIBUTES field of the SECS. On enclave creation (ENCLU[ECREATE] leaf function), the required SSA frame size is calculated by the processor from the list of enabled extended and miscellaneous states and verified against the actual SSA frame size defined by SECS.SSAFRAMESIZE.

On enclave entry, after verifying that XFRM is only enabling features that are already enabled in XCR0, the value in the XCR0 is saved internally by the processor, and is replaced by the XFRM. On enclave exit, the original value of XCR0 is restored. Consequently, while inside the enclave, the processor extended states enabled in XFRM are in enabled state, and those that are disabled in XFRM are in disabled state.

The entire ATTRIBUTES field, including the XFRM subfield is integral part of enclave's identity (i.e., its value is included in reports generated by ENCLU[EREPORT], and select bits from this field can be included in key-derivation for keys obtained via the ENCLU[EGETKEY] leaf function).

Enclave developers can create their enclave to work with certain features and fallback to another code path in case those features aren't available (e.g., optimize for AVX and fallback to SSE). For this purpose Intel SGX provides the following fields in SIGSTRUCT: ATTRIBUTES, ATTRIBUTESMASK, MISCSELECT, and MISCMASK. EINIT ensures that the final SECS.ATTRIBUTES and SECS.MISCSELECT comply with the enclave developer's requirements as follows:

SIGSTRUCT.ATTRIBUTES & SIGSTRUCT.ATTRIBUTESENABLED = SECS.ATTRIBUTES & SIGSTRUCT.ATTRIBUTESENABLED

SIGSTRUCT.MISCSELECT & SIGSTRUCT.MISCMASK = SECS.MISCSELECT & SIGSTRUCT.MISCMASK.

On an asynchronous enclave exit, the processor extended states enabled by XFRM are saved in the current SSA frame, and overwritten by synthetic state (see Section 37.3 for the definition of the synthetic state). When the interrupted enclave is resumed via the ENCLU[ERESUME] leaf function, the saved state for processor extended states enabled by XFRM is restored.

## 39.7.2 Relevant Fields in Various Data Structures

### 39.7.2.1 SECS.ATTRIBUTES.XFRM

The ATTRIBUTES field of the SECS data structure (see Section 35.7) contains a sub-field called XSAVE-Feature Request Mask (XFRM). Software populates this field at the time of enclave creation according to the features that are enabled by the operating system and approved by the enclave developer.

Intel SGX architecture guarantees that during enclave execution, the processor extended state configuration of the processor is identical to what is required by the XFRM sub-field. All the processor extended states enabled in XFRM are saved on AEX from the enclave and restored on ERESUME.

The XFRM sub-field has the same layout as XCR0, and has consistency requirements that are similar to those for XCR0. Specifically, the consistency requirements on XFRM values depend on the processor implementation and the set of features enabled in CR4.

Legal values for SECS.ATTRIBUTES.XFRM conform to these requirements:

- XFRM[1:0] must be set to 0x3.
- If the processor does not support XSAVE, or if the system software has not enabled XSAVE, then XFRM[63:2] must be zero.
- If the processor does support XSAVE, XFRM must contain a value that would be legal if loaded into XCR0.

The various consistency requirements are enforced at different times in the enclave's life cycle, and the exact enforcement mechanisms are elaborated in Section 39.7.3 through Section 39.7.6.

On processors not supporting XSAVE, software should initialize XFRM to 0x3. On processors supporting XSAVE, software should initialize XFRM to be a subset of XCR0 that would be present at the time of enclave execution.

Because bits 0 and 1 of XFRM must always be set, the use of Intel SGX requires that SSE be enabled (CR4.OSFXSR = 1).

### 39.7.2.2 SECS.SSAFRAMESIZE

The SSAFRAMESIZE field in the SECS data structure specifies the number of pages which software allocated<sup>1</sup> for each SSA frame, including both the GPRSGX area, MISC area, the XSAVE area (x87 and XMM states are stored in the latter area), and optionally padding between the MISC and XSAVE area. The GPRSGX area must hold all the general-purpose registers and additional Intel SGX specific information. The MISC area must hold the Miscellaneous state as specified by SECS.MISCSELECT, the XSAVE area holds the set of processor extended states specified by SECS.ATTRIBUTES.XFRM (see Section 35.9 for the layout of SSA and Section 39.7.3 for ECREATE's consistency checks). The SSA is always in non-compacted format.

If the processor does not support XSAVE, the XSAVE area will always be 576 bytes; a copy of XFRM (which will be set to 0x3) is saved at offset 512 on an AEX.

If the processor does support XSAVE, the length of the XSAVE area depends on SECS.ATTRIBUTES.XFRM. The length would be equal to what CPUID.(EAX=0DH, ECX= 0):EBX would return if XCR0 were set to XFRM. The following pseudo code illustrates how software can calculate this length using XFRM as the input parameter without modifying XCR0:

```

offset = 576;
size_last_x = 0;
For x=2 to 63
 IF (XFRM[x] != 0) Then
 tmp_offset = CPUID.(EAX=0DH, ECX= x):EBX[31:0];
 IF (tmp_offset >= offset + size_last_x) Then
 offset = tmp_offset;
 size_last_x = CPUID.(EAX=0DH, ECX= x):EAX[31:0];
 FI;
FI;
EndFor
return (offset + size_last_x); (* compute_xsave_size(XFRM), see "ECREATE—Create an SECS page in the Enclave Page Cache"*)

```

Where the non-zero bits in XFRM are a subset of non-zero bit fields in XCR0.

The size of the MISC region depends on the setting of SECS.MISCSELECT and can be calculated using the layout information described in Section 35.9.2

### 39.7.2.3 XSAVE Area in SSA

The XSAVE area of an SSA frame begins at offset 0 of the frame.

### 39.7.2.4 MISC Area in SSA

The MISC area of an SSA frame is positioned immediately before the GPRSGX region.

### 39.7.2.5 SIGSTRUCT Fields

Intel SGX provides the flexibility for an enclave developer to choose the enclave's code path according to the features that are enabled on the platform (e.g., optimize for AVX and fallback to SSE). See Section 39.7.1 for details.

---

1. It is the responsibility of the enclave to actually allocate this memory.

SIGSTRUCT includes the following fields:

SIGSTRUCT.ATTRIBUTES, SIGSTRUCT.ATTRIBUTEMASK, SIGSTRUCT.MISCSELECT, SIGSTRUCT.MISCMASK.

### 39.7.2.6 REPORT.ATTRIBUTES.XFRM and REPORT.MISCSELECT

The processor extended states and miscellaneous states that are enabled inside the enclave form an integral part of the enclave's identity and are therefore included in the enclave's report, as provided by the ENCLU[EREPORT] leaf function. The REPORT structure includes the enclave's XFRM and MISCSELECT configurations.

### 39.7.2.7 KEYREQUEST

An enclave developer can specify which bits out of XFRM and MISCSELECT ENCLU[EGETKEY] should include in the derivation of the sealing key by specifying ATTRIBUTEMASK and MISCMASK in the KEYREQUEST structure.

## 39.7.3 Processor Extended States and ENCLS[ECREATE]

The ECREATE leaf function of the ENCLS instruction enforces a number of consistency checks described earlier. The execution of ENCLS[ECREATE] leaf function results in a #GP(0) in any of the following cases:

- SECS.ATTRIBUTES.XFRM[1:0] is not 3.
- The processor does not support XSAVE and any of the following is true:
  - SECS.ATTRIBUTES.XFRM[63:2] is not 0.
  - SECS.SSAFRAMESIZE is 0.
- The processor supports XSAVE and any of the following is true:
  - XSETBV would fault on an attempt to load XFRM into XCR0.
  - XFRM[63]=1.
  - The SSAFRAME is too small to hold required, enabled states (see Section 39.7.2.2).

## 39.7.4 Processor Extended States and ENCLU[EENTER]

### 39.7.4.1 Fault Checking

The EENTER leaf function of the ENCLU instruction enforces a number of consistency requirements described earlier. The execution of the ENCLU[EENTER] leaf function results in a #GP(0) in any of the following cases:

- If CR4.OSFXSR=0.
- If The processor supports XSAVE and either of the following is true:
  - CR4.OSXSAVE=0 and SECS.ATTRIBUTES.XFRM is not 3.
  - (SECS.ATTRIBUTES.XFRM & XCR0) != SECS.ATTRIBUTES.XFRM

### 39.7.4.2 State Loading

If ENCLU[EENTER] is successful, the current value of XCR0 is saved internally by the processor and replaced by SECS.ATTRIBUTES.XFRM.

## 39.7.5 Processor Extended States and AEX

### 39.7.5.1 State Saving

On an AEX, processor extended states are saved into the XSAVE area of the SSA frame in a compatible format with XSAVE that was executed with EDX:EAX = SECS.ATTRIBUTES.XFRM, with the memory operand being the XSAVE area, and (for 64-bit enclaves) as if REX.W=1. The XSTATE\_BV part of the XSAVE header is saved with 0 for every bit that is 0 in XFRM. Other bits may be saved as 0 if the state saved is initialized.

Note that enclave entry ensures that if CR4.OSXSAVE is set to 0, then SECS.ATTRIBUTES.XFRM is set to 3. It should also be noted that it is not possible to enter an enclave with FXSAVE disabled.

### 39.7.5.2 State Synthesis

After saving the extended state, the processor restores XCR0 to the value it held at the time of the most recent enclave entry.

The state of features corresponding to bits set in XFRM is synthesized. In general, these states are initialized. Details of state synthesis on AEX are documented in Section 37.3.1.

## 39.7.6 Processor Extended States and ENCLU[ERESUME]

### 39.7.6.1 Fault Checking

The ERESUME leaf function of the ENCLU instruction enforces a number of consistency requirements described earlier. Specifically, the ENCLU[ERESUME] leaf function results in a #GP(0) in any of the following cases:

- CR4.OSFXSR=0.
- The processor supports XSAVE and either of the following is true:
  - CR4.OSXSAVE=0 and SECS.ATTRIBUTES.XFRM is not 3.
  - (SECS.ATTRIBUTES.XFRM & XCR0) != SECS.ATTRIBUTES.XFRM.

A successful execution of ENCLU[ERESUME] loads state from the XSAVE area of the SSA frame in a fashion similar to that used by the XRSTOR instruction. Data in the XSAVE area that would cause the XRSTOR instruction to fault will cause the ENCLU[ERESUME] leaf function to fault. Examples include, but are not restricted to the following:

- A bit is set in the XSTATE\_BV field and clear in XFRM.
- The required bytes in the header are not clear.
- Loading data would set a reserved bit in MXCSR.

Any of these conditions will cause ERESUME to fault, even if CR4.OSXSAVE=0.

### 39.7.6.2 State Loading

If ENCLU[ERESUME] is successful, the current value of XCR0 is saved internally by the processor and replaced by SECS.ATTRIBUTES.XFRM.

State is loaded from the XSAVE area of the SSA frame as if the XRSTOR instruction were executed with XCR0=XFRM, EDX:EAX = XFRM, with the memory operand being the XSAVE area, and (for 64-bit enclaves) as if REX.W=1.

ENCLU[ERESUME] ensures that a subsequent execution of XSAVEOPT inside the enclave will operate properly (e.g., by marking all state as modified).

## 39.7.7 Processor Extended States and ENCLU[EEXIT]

The ENCLU[EEXIT] leaf function does not perform any X-feature specific consistency checks, nor performs any state synthesis. It is the responsibility of enclave software to clear any sensitive data from the registers before

executing EEXIT. However, successful execution of the ENCLU[EEXIT] leaf function restores XCR0 to the value it held at the time of the most recent enclave entry.

### 39.7.8 Processor Extended States and ENCLU[EREPORT]

The ENCLU[EREPORT] leaf function creates the MAC-protected REPORT structure that reports on the enclave's identity. ENCLU[EREPORT] includes in the report the values of SECS.ATTRIBUTES.XFRM and SECS.MISCSELECT.

### 39.7.9 Processor Extended States and ENCLU[EGETKEY]

The ENCLU[EGETKEY] leaf function returns a cryptographic key based on the information provided by the KEYREQUEST structure. Intel SGX provides the means for isolation between different operating conditions by allowing an enclave developer to select which bits out of XFRM and MISCSELECT need to be included in the derivation of the keys.

## 39.8 INTERACTIONS WITH SMM

### 39.8.1 Availability of Intel® SGX instructions in SMM

Enclave instructions are not available in SMM, and any attempt to execute ENCLS or ENCLU instructions inside SMM results in an invalid-opcode exception (#UD).

### 39.8.2 SMI while Inside an Enclave

If the logical processor executing inside an enclave receives an SMI, the logical processor exits the enclave asynchronously. The response to an SMI received while executing inside an enclave depends on whether the dual-monitor treatment is enabled. For detailed discussion of transfer to SMM, see Chapter 32, "System Management Mode" of the Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3C.

If the logical processor executing inside an enclave receives an SMI when dual-monitor treatment is not enabled, the logical processor exits the enclave asynchronously, and transfers the control to the SMM handler. In addition to saving the synthetic architectural state to the SMRAM State Save Map (SSM), the logical processor also sets the "Enclave Interruption" bit in the SMRAM SSM (bit position 1 in SMRAM field at offset 7EE0H).

If the logical processor executing inside an enclave receives an SMI when dual-monitor treatment is enabled, the logical processor exits the enclave asynchronously, and transfers the control to the SMM monitor via SMM VM exit. The SMM VM exit sets the "Enclave Interruption" bit in the Exit Reason (see Table 39-2) and in the Guest Interruptibility State field (see Table 39-3) of the SMM VMCS.

### 39.8.3 SMRAM Synthetic State of AEX Triggered by SMI

All processor registers saved in the SMRAM have the same synthetic values listed in Section 37.3. Additional SMRAM fields that are treated specially on SMI are:

**Table 39-2. SMRAM Synthetic States on Asynchronous Enclave Exit**

| Position                  | Field             | Value                                     | Writable |
|---------------------------|-------------------|-------------------------------------------|----------|
| SMRAM Offset 07EE0H.Bit 1 | ENCLAVE_INTERRUPT | Set to 1 if exit occurred in enclave mode | No       |

## 39.9 INTERACTIONS OF INIT, SIPI, AND WAIT-FOR-SIPI WITH INTEL® SGX

INIT received inside an enclave, while the logical processor is not in VMX operation, causes the logical processor to exit the enclave asynchronously. After the AEX, the processor's architectural state is initialized to "Power-on" state (Table 9.1 in Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A). If the logical processor is BSP, then it proceeds to execute the BIOS initialization code. If the logical processor is an AP, it enters wait-for-SIPI state.

INIT received inside an enclave, while the logical processor (LP) is in VMX root operation, follows regular Intel Architecture behavior and is blocked.

INIT received inside an enclave, while the logical processor is in VMX non-root operation, causes an AEX. Subsequent to the AEX, the INIT causes a VM exit with the Enclave Interruption bit in the exit-reason field in the VMCS.

A processor cannot be inside an enclave in the wait-for-SIPI state. Consequently, a SIPI received while inside an enclave is lost.

Intel SGX does not change the behavior of the processor in the wait-for-SIPI state.

The SGX-related processor states after INIT-SIPI-SIPI is as follows:

- EPC Settings: Unchanged
- EPCM: Unchanged
- CPUID.LEAF\_12H.\*: Unchanged
- ENCLAVE\_MODE: 0 (LP exits enclave asynchronously)
- MEE state: Unchanged

Software should be aware that following INIT-SIPI-SIPI, the EPC might contain valid pages and should take appropriate measures such as initialize the EPC with the EREMOVE leaf function.

## 39.10 INTERACTIONS WITH DMA

DMA is not allowed to access any Processor Reserved Memory.

## 39.11 INTERACTIONS WITH TXT

### 39.11.1 Enclaves Created Prior to Execution of GETSEC

Enclaves which have been created before the GETSEC[SENTER] leaf function are available for execution after the successful completion of GETSEC[SENTER] and the corresponding SINIT ACM. Actions that a TXT Launched Environment performs in preparation to execute code in the Launched Environment, also applies to enclave code that would run after GETSEC[SENTER].

### 39.11.2 Interaction of GETSEC with Intel® SGX

All leaf functions of the GETSEC instruction are illegal inside an enclave, and results in an invalid-opcode exception (#UD).

Responding Logical Processors (RLP) which are executing inside an enclave at the time a GETSEC[SENTER] event occurs perform an AEX from the enclave and then enter the Wait-for-SIPI state.

RLP executing inside an enclave at the time of GETSEC[SEXIT], behave as defined for GETSEC[SEXIT]-that is, the RLPs pause during execution of SEXIT and resume after the completion of SEXIT.

The execution of a TXT launch does not affect Intel SGX configuration or security parameters.

### 39.11.3 Interactions with Authenticated Code Modules (ACMs)

Intel SGX only allows launching ACMs with an Intel SGX SVN that is at the same level or higher than the expected Intel SGX SVN. The expected Intel SGX SVN is specified by BIOS and locked down by the processor on the first successful execution of an Intel SGX instruction that doesn't return an error code. Intel SGX provides interfaces for system software to discover whether a non faulting Intel SGX instruction has been executed, and evaluate the suitability of the Intel SGX SVN value of any ACM that is expected to be launched by the OS or the VMM.

These interfaces are provided through a read-only MSR called the IA32\_SGX SVN\_STATUS MSR (MSR address 500h). The IA32\_SGX SVN\_STATUS MSR has the format shown in Table 39-3.

**Table 39-3. Layout of the IA32\_SGX SVN\_STATUS MSR**

| Bit Position | Name          | ACM Module ID | Value                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|---------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | Lock          | N.A.          | <ul style="list-style-type: none"> <li>▪ If 1, indicates that a non-faulting Intel SGX instruction has been executed, consequently, launching a properly signed ACM but with Intel SGX SVN value less than the BIOS specified Intel SGX SVN threshold would lead to an TXT shutdown.</li> <li>▪ If 0, indicates that the processor will allow a properly signed ACM to launch irrespective of the Intel SGX SVN value of the ACM.</li> </ul> |
| 15:1         | RSVD          | N.A.          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 23:16        | SGX SVN_SINIT | SINIT ACM     | <ul style="list-style-type: none"> <li>▪ If CPUID.01H:ECX.SMX =1, this field reflects the expected threshold of Intel SGX SVN for the SINIT ACM.</li> <li>▪ If CPUID.01H:ECX.SMX =0, this field is reserved (0).</li> </ul>                                                                                                                                                                                                                  |
| 63:24        | RSVD          | N.A.          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                            |

OS/VMM that wishes to launch an architectural ACM such as SINIT is expected to read the IA32\_SGX SVN\_STATUS MSR to determine whether the ACM can be launched or a new ACM is needed:

- If either the Intel SGX SVN of the ACM is greater than the value reported by IA32\_SGX SVN\_STATUS, or the lock bit in the IA32\_SGX SVN\_STATUS is not set, then the OS/VMM can safely launch the ACM.
- If the Intel SGX SVN value reported in the corresponding component of the IA32\_SGX SVN\_STATUS is greater than the Intel SGX SVN value in the ACM's header, and if bit 0 of IA32\_SGX SVN\_STATUS is 1, then the OS/VMM should not launch that version of the ACM. It should obtain an updated version of the ACM either from the BIOS or from an external resource.

However, OSVs/VMMs are strongly advised to update their version of the ACM any time they detect that the Intel SGX SVN of the ACM carried by the OS/VMM is lower than that reported by IA32\_SGX SVN\_STATUS MSR, irrespective of the setting of the lock bit.

## 39.12 INTERACTIONS WITH CACHING OF LINEAR-ADDRESS TRANSLATIONS

Entering and exiting an enclave causes the logical processor to flush all the global linear-address context as well as the linear-address context associated with the current VPID and PCID. The MONITOR FSM is also cleared.

## 39.13 INTERACTIONS WITH INTEL® TRANSACTIONAL SYNCHRONIZATION EXTENSIONS (INTEL® TSX)

1. ENCLU or ENCLS instructions inside an HLE region will cause the flow to be aborted and restarted non-speculatively. ENCLU or ENCLS instructions inside an RTM region will cause the flow to be aborted and transfer control to the fallback handler.
2. If XBEGIN is executed inside an enclave, the processor does NOT check whether the address of the fallback handler is within the enclave.
3. If an RTM transaction is executing inside an enclave and there is an attempt to fetch an instruction outside the enclave, the transaction is aborted and control is transferred to the fallback handler. No #GP is delivered.

4. If an RTM transaction is executing inside an enclave and there is a data access to an address within the enclave that denied due to EPCM content (e.g., to a page belonging to a different enclave), the transaction is aborted and control is transferred to the fallback handler. No #GP is delivered.

5. If an RTM transaction executing inside an enclave aborts and the address of the fallback handler is outside the enclave, a #GP is delivered after the abort (EIP reported is that of the fallback handler).

### 39.13.1 HLE and RTM Debug

RTM debug will be suppressed on opt-out enclave entry. After opt-out entry, the logical processor will behave as if IA32\_DEBUG\_CTL[15]=0. Any #DB detected inside an RTM transaction region will just cause an abort with no exception delivered.

After opt-in entry, if either DR7[11] = 0 OR IA32\_DEBUGCTL[15] = 0, any #DB or #BP detected inside an RTM transaction region will just cause an abort with no exception delivered.

After opt-in entry, if DR7[11] = 1 AND IA32\_DEBUGCTL[15] = 1, any #DB or #BP detected inside an RTM translation will

- terminate speculative execution,
- set RIP to the address of the XBEGIN instruction, and
- be delivered as #DB (implying an Intel SGX AEX; any #BP is converted to #DB).
- DR6[16] will be cleared, indicating RTM debug (if the #DB causes a VM exit, DR6 is not modified but bit 16 of the pending debug exceptions field in the VMCS will be set).

## 39.14 INTEL® SGX INTERACTIONS WITH S STATES

Whenever an Intel SGX enabled processor enters S3-S5 state, enclaves are destroyed. This is due to the EPC being destroyed when power down occurs. It is the application runtime's responsibility to re-instantiate an enclave after a power transition for which the enclaves were destroyed.

## 39.15 INTEL® SGX INTERACTIONS WITH MACHINE CHECK ARCHITECTURE (MCA)

### 39.15.1 Interactions with MCA Events

All architecturally visible machine check events (#MC and CMCI) that are detected while inside an enclave cause an asynchronous enclave exit.

Any machine check exception (#MC) that occurs after Intel SGX is first enables causes Intel SGX to be disabled, (CPUID.SGX\_Leaf.0:EAX[SGX1] == 0). It cannot be enabled until after the next reset.

### 39.15.2 Machine Check Enables (IA32\_MCI\_CTL)

All supported IA32\_MCI\_CTL bits for all the machine check banks must be set for Intel SGX to be available (CPUID.SGX\_Leaf.0:EAX[SGX1] == 1). Any act of clearing bits from '1 to '0 in any of the IA32\_MCI\_CTL register may disable Intel SGX (set CPUID.SGX\_Leaf.0:EAX[SGX1] to 0) until the next reset.

### 39.15.3 CR4.MCE

CR4.MCE can be set or cleared with no interactions with Intel SGX.

## 39.16 INTEL® SGX INTERACTIONS WITH PROTECTED MODE VIRTUAL INTERRUPTS

ENCLS[EENTER] modifies neither EFLAGS.VIP nor EFLAGS.VIF.

ENCLS[ERESUME] loads EFLAGS in a manner similar to that of an execution of IRET with CPL = 3. This means that ERESUME modifies neither EFLAGS.VIP nor EFLAGS.VIF regardless of the value of the EFLAGS image in the SSA frame.

AEX saves EFLAGS.VIP and EFLAGS.VIF unmodified into the EFLAGS image in the SSA frame. AEX modifies neither EFLAGS.VIP nor EFLAGS.VIF after saving EFLAGS.

If CR4.PVI = 1, CPL = 3, EFLAGS.VM = 0, IOPL < 3, EFLAGS.VIP = 1, and EFLAGS.VIF = 0, execution of STI causes a #GP fault. In this case, STI modifies neither EFLAGS.IF nor EFLAGS.VIF. This behavior applies without change within an enclave (where CPL is always 3). Note that, if IOPL = 3, STI always sets EFLAGS.IF without fault; CR4.PVI, EFLAGS.VIP, and EFLAGS.VIF are neither consulted nor modified in this case.

## 39.17 INTEL SGX INTERACTION WITH PROTECTION KEYS

SGX interactions with PKRU are as follows:

- CPUID.(EAX=12H, ECX=1):ECX.PKRU indicates whether SECS.ATTRIBUTES.XFRM.PKRU can be set. If SECS.ATTRIBUTES.XFRM.PKRU is set, then PKRU is saved and cleared as part of AEX and is restored as part of ERESUME. If CR4.PKE is set, an enclave can execute RDPKRU and WRKRU independent of whether SECS.ATTRIBUTES.XFRM.PKRU is set.

SGX interactions with domain permission checks are as follows:

- 1) If CR4.PKE is not set, then legacy and SGX permission checks are not effected.
- 2) If CR4.PKE is set, then domain permission checks are applied to all non-enclave access and enclave accesses to user pages in addition to legacy and SGX permission checks at a higher priority than SGX permission checks.
- 3) Implicit accesses aren't subject to domain permission checks.

# CHAPTER 40

## ENCLAVE CODE DEBUG AND PROFILING

---

Intel® SGX is architected to provide protection for production enclaves and permit enclave code developers to use an SGX-aware debugger to effectively debug a non-production enclave (debug enclave). Intel SGX also allows a non-SGX-aware debugger to debug non-enclave portions of the application without getting confused by enclave instructions.

## 40.1 CONFIGURATION AND CONTROLS

### 40.1.1 Debug Enclave vs. Production Enclave

The SECS of each enclave provides a bit, SECS.ATTRIBUTES.DEBUG, indicating whether the enclave is a debug enclave (if set) or a production enclave (if 0). If this bit is set, software outside the enclave can use EDBGWR to access the EPC memory of the enclave. The value of DEBUG is not included in the measurement of the enclave and therefore doesn't require an alternate SIGSTRUCT to be generated to debug the enclave.

The ATTRIBUTES field in the SECS is reported in the enclave's attestation, and is included in the key derivation. Enclave secrets that were protected by the enclave using Intel SGX keys when it ran as a production enclave will not be accessible by the debug enclave. A debugger needs to be aware that special debug content might be required for a debug enclave to run in a meaningful way.

EPC memory belonging to a debug enclave can be accessed via the EDBGWR leaf functions (see Section 38.4), while that belonging to a non-debug enclave cannot be accessed by these leaf functions.

### 40.1.2 Tool-Chain Opt-in

The TCS.FLAGS.DBGOPTIN bit controls interactions of certain debug and profiling features with enclaves, including code/data breakpoints, TF, RF, monitor trap flag, BTF, LBRs, BTM, BTS, Intel Processor Trace, and performance monitoring. This bit is forced to zero when EPC pages are added via EADD. A debugger can set this bit via EDBGWR to the TCS of a debug enclave.

An enclave entry through a TCS with the TCS.FLAGS.DBGOPTIN set to 0 is called an **opt-out entry**. Conversely, an enclave entry through a TCS with TCS.FLAGS.DBGOPTIN set to 1 is called an **opt-in entry**.

### 40.1.3 Debugging an Enclave That Uses Asynchronous Enclave Exit Notify

Whenever an opt-in enclave entry is used to perform enclave code debugging or profiling, the debugger or profiling tool may clear TCS.FLAGS.AEXNOTIFY to prevent AEX notifications from being delivered at each interrupt, breakpoint, trap, or other exception.

## 40.2 SINGLE STEP DEBUG

### 40.2.1 Single Stepping ENCLS Instruction Leafs

If the RFLAGS.TF bit is set at the beginning of ENCLS, then a single-step debug exception is pending as a trap-class exception on the instruction boundary immediately after the ENCLS instruction. Additionally, if the instruction is executed in VMX non-root operation and the "monitor trap flag" VM-execution control is 1, an MTF VM exit is pending on the instruction boundary immediately after the instruction if the instruction does not fault.

## 40.2.2 Single Stepping ENCLU Instruction Leafs

The interactions of the unprivileged Intel SGX instruction ENCLU are leaf dependent.

An enclave entry via EENTER/ERESUME leaf functions of the ENCLU, in certain cases, may mask the RFLAGS.TF bit, and mask the setting of the “monitor trap flag” VM-execution control. In such situations, an exit from the enclave, either via the EEXIT leaf function or via an AEX unmasks the RFLAGS.TF bit and the “monitor trap flag” VM-execution control. The details of this masking/unmasking and the pending of single stepping events across EENTER/ERESUME/EEXIT/AEX are covered in detail in Section 40.2.3.

If the EFLAGS.TF bit is set at the beginning of EREPORT or EGETKEY leafs, and if the EFLAGS.TF is not masked by the preceding enclave entry, then a single-step debug exception is pending on the instruction boundary immediately after the ENCLU instruction. Additionally, if the instruction is executed in VMX non-root operation and the “monitor trap flag” VM-execution control is 1, and if the monitor trap flag is not masked by the preceding enclave entry, then an MTF VM exit is pending on the instruction boundary immediately after the instruction.

If the instruction under consideration results in a fault, then the control flow goes to the fault handler, and no single-step debug exception is asserted. In such a situation, if the instruction is executed in VMX non-root operation and the “monitor trap flag” VM-execution control is 1, an MTF VM exit is pending after the delivery of the fault (or any nested exception). No MTF VM exit occurs if another VM exit occurs before reaching that boundary on which an MTF VM exit would be pending.

## 40.2.3 Single-Stepping Enclave Entry with Opt-out Entry

### 40.2.3.1 Single Stepping without AEX

Figure 40-1 shows the most common case for single-stepping after an opt-out entry.

**Figure 40-1. Single Stepping with Opt-out Entry - No AEX**

In this scenario, if the RFLAGS.TF bit is set at the time of the enclave entry, then a single step debug exception is pending on the instruction boundary after EEXIT. Additionally, if the enclave is executing in VMX non-root operation and the “monitor trap flag” VM-execution control is 1, an MTF VM exit is pending on the instruction boundary after EEXIT.

The value of the RFLAGS.TF bit at the end of EEXIT is the same as the value of RFLAGS.TF at the time of the enclave entry.

### 40.2.3.2 Single Step Preempted by AEX Due to Non-SMI Event

Figure 40-2 shows the interaction of single stepping with AEX due to a non-SMI event after an opt-out entry.

**Figure 40-2. Single Stepping with Opt-out Entry -AEX Due to Non-SMI Event Before Single-Step Boundary**

In this scenario, if the enclave is executing in VMX non-root operation and the “monitor trap flag” VM-execution control is 1, an MTF VM exit is pending on the instruction boundary after the AEX. No MTF VM exit occurs if another VM exit happens before reaching that instruction boundary.

The value of the RFLAGS.TF bit at the end of AEX is the same as the value of RFLAGS.TF at the time of the enclave entry.

#### 40.2.4 RFLAGS.TF Treatment on AEX

The value of EFLAGS.TF at the end of AEX from an opt-out enclave is same as the value of EFLAGS.TF at the time of the enclave entry. The value of EFLAGS.TF at the end of AEX from an opt-in enclave is unmodified. The EFLAGS.TF saved in GPR portion of the SSA on an AEX is 0. For more detail see EENTER and ERESUME in Chapter 5.

#### 40.2.5 Restriction on Setting of TF after an Opt-Out Entry

Enclave entered through an opt-out entry is not allowed to set EFLAGS.TF. The POPF instruction forces RFLAGS.TF to 0 if the enclave was entered through opt-out entry.

#### 40.2.6 Trampoline Code Considerations

Any AEX from the enclave which results in the RFLAGS.TF =1 on the reporting stack will result in a single-step #DB after the first instruction of the trampoline code if the trampoline is entered using the IRET instruction.

### 40.3 CODE AND DATA BREAKPOINTS

#### 40.3.1 Breakpoint Suppression

Following an opt-out entry:

- Instruction breakpoints are suppressed during execution in an enclave.
- Data breakpoints are not triggered on accesses to the address range defined by ELRANGE.
- Data breakpoints are triggered on accesses to addresses outside the ELRANGE

Following an opt-in entry instruction and data breakpoints are not suppressed.

The processor does not report any matches on debug breakpoints that are suppressed on enclave entry. However, the processor does not clear any bits in DR6 that were already set at the time of the enclave entry.

### 40.3.2 Reporting of Instruction Breakpoint on Next Instruction on a Debug Trap

A debug exception caused by the single-step execution mode or when a data breakpoint condition was met causes the processor to perform an AEX. Following such an AEX, the processor reports in the debug status register (DR6) matches of the new instruction pointer (the AEP address) in a breakpoint address register setup to detect instruction execution.

### 40.3.3 RF Treatment on AEX

RF flag value saved in SSA is the same as what would have been pushed on stack if the exception or event causing the AEX occurred when executing outside an enclave (see Section 18.3.1.1). Following an AEX, the RF flag is 0 in the synthetic state.

### 40.3.4 Breakpoint Matching in Intel® SGX Instruction Flows

Implicit accesses made by Intel SGX instructions to EPC regions do not trigger data breakpoints. Explicit accesses made by ENCLS[ECREATE], ENCLS[EADD], ENCLS[EEXTEND], ENCLS[EINIT], ENCLS[EREMOVE], ENCLS[ETRACK], ENCLS[EBLOCK], ENCLS[EPA], ENCLS[EWB], ENCLS[ELD], ENCLS[EDBGRD], ENCLS[EDBGWR], ENCLU[EENTER], and ENCLU[ERESUME] to the EPC operands do not trigger data breakpoints.

Explicit accesses made by the Intel SGX instructions (ENCLU[EGETKEY] and ENCLU[EREPORT]) executed by an enclave following an opt-in entry, trigger data breakpoints on accesses to their EPC operands. All Intel SGX instructions trigger data breakpoints on accesses to their non-EPC operands.

## 40.4 CONSIDERATION OF THE INT1 AND INT3 INSTRUCTIONS

This section considers the operation of the INT1 and INT3 instructions when executed inside an enclave. These are the instructions with opcodes F1 and CC, respectively, and not INT *n* (with opcode CD) with value 1 or 3 for *n*.

### 40.4.1 Behavior of INT1 and INT3 Inside an Enclave

An execution of either INT1 or INT3 inside an enclave results in a fault-class exception. Following an opt-out entry, execution of either instruction results in an invalid-opcode exception (#UD). Following opt-in entry, INT1 results in a debug exception (#DB) and INT3 delivers a breakpoint exception (#BP). The normal requirement for INT3 (that the CPL not be greater than the DPL of descriptor 3 in the IDT) is not enforced.

Because execution of INT1 or INT3 inside an enclave results in a fault, the RIP saved in the SSA on AEX references the INT1 or INT3 instruction (and not the following instruction). The RIP value saved on the stack (or in the TSS or VMCS) is that of the AEP.

If execution of INT1 or INT3 inside an enclave causes a VM exit, the event type in the VM-exit interruption information field indicates a hardware exception (type 3),<sup>1</sup> and the VM-exit instruction length field is saved as zero.

### 40.4.2 Debugger Considerations

A debugger using INT3 inside an enclave should account for the modified behavior described in Section 40.4.1. Because INT3 is fault-like inside an enclave, the RIP saved in the SSA on AEX is that of the INT3 instruction. Conse-

---

1. INT1 would normally indicate a privileged software exception (type 5), and INT3 would normally indicate a software exception (type 6).

quently, the debugger must not decrement SSA.RIP for #BP coming from an enclave to re-execute the instruction at the RIP of the INT3 instruction on a subsequent enclave entry.

### 40.4.3 VMM Considerations

As described in Section 40.4.1, execution of INT3 inside an enclave delivers #BP with “interruption type” of 3. A VMM that re-injects #BP into the guest should establish the VM-entry interruption information field using data saved into the appropriate VMCS fields by the VM exit incident to the #BP (as recommended in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3C).

VMMs that create the VM-entry interruption information based solely on the exception vector should take care to use event type 3 (instead of 6) when they detect a VM exit incident to enclave mode that is due to an exception with vector 3.

## 40.5 BRANCH TRACING

### 40.5.1 BTF Treatment

When software enables single-stepping on branches then:

- Following an opt-in entry using EENTER the processor generates a single step debug exception.
- Following an EEXIT the processor generates a single-step debug exception

Enclave entry using ERESUME (opt-in or opt-out) and an AEX from the enclave do not cause generation of the single-step debug exception.

### 40.5.2 LBR Treatment

#### 40.5.2.1 LBR Stack on Opt-in Entry

Following an opt-in entry into an enclave, last branch recording facilities if enabled continued to store branch records in the LBR stack MSRs as follows:

- On enclave entry using EENTER/ERESUME, the processor push the address of EENTER/ERESUME instruction into MSR\_LASTBRANCH\_n\_FROM\_IP, and the destination address of the EENTER/ERESUME into MSR\_LASTBRANCH\_n\_TO\_IP.
- On EEXIT, the processor pushes the address of EEXIT instruction into MSR\_LASTBRANCH\_n\_FROM\_IP, and the address of EEXIT destination into MSR\_LASTBRANCH\_n\_TO\_IP.
- On AEX, the processor pushes RIP saved in the SSA into MSR\_LASTBRANCH\_n\_FROM\_IP, and the address of AEP into MSR\_LASTBRANCH\_n\_TO\_IP.
- For every branch inside the enclave, a branch record is pushed on the LBR stack.

Figure 40-3 shows an example of LBR stack manipulation after an opt-in entry. Every arrow in this picture indicates a branch record pushed on the LBR stack. The “From IP” of the branch record contains the linear address of the instruction located at the start of the arrow, while the “To IP” of the branch record contains the linear address of the instruction at the end of the arrow.

Figure 40-3. LBR Stack Interaction with Opt-in Entry

#### 40.5.2.2 LBR Stack on Opt-out Entry

An opt-out entry into an enclave suppresses last branch recording facilities, and enclave exit after an opt-out entry un-suppresses last branch recording facilities.

Opt-out entry into an enclave does not push any record on LBR stack.

If last branch recording facilities were enabled at the time of enclave entry, then EEXIT following such an enclave entry pushes one record on LBR stack. The MSR\_LASTBRANCH\_n\_FROM\_IP of such record holds the linear address of the instruction (EENTER or ERESUME) that was used to enter the enclave, while the MSR\_LASTBRANCH\_n\_TO\_IP of such record holds linear address of the destination of EEXIT.

Additionally, if last branch recording facilities were enabled at the time of enclave entry, then an AEX after such an entry pushes one record on LBR stack, before pushing record for the event causing the AEX if the event pushes a record on LBR stack. The MSR\_LASTBRANCH\_n\_FROM\_IP of the new record holds linear address of the instruction (EENTER or ERESUME) that was used to enter the enclave, while MSR\_LASTBRANCH\_n\_TO\_IP of the new record holds linear address of the AEP. If the event causing AEX pushes a record on LBR stack, then the MSR\_LASTBRANCH\_n\_FROM\_IP for that record holds linear address of the AEP.

Figure 40-4 shows an example of LBR stack manipulation after an opt-out entry. Every arrow in this picture indicates a branch record pushed on the LBR stack. The "From IP" of the branch record contains the linear address of the instruction located at the start of the arrow, while the "To IP" of the branch record contains the linear address of the instruction at the end of the arrow.

Figure 40-4. LBR Stack Interaction with Opt-out Entry

#### 40.5.2.3 Mispredict Bit, Record Type, and Filtering

All branch records resulting from Intel SGX instructions/AEXs are reported as predicted branches, and consequently, bit 63 of MSR\_LASTBRANCH\_n\_FROM\_IP for such records is set. Branch records due to these Intel SGX operations are always non-HLE/non-RTM records.

EENTER, ERESUME, EEXIT, and AEX are considered to be far branches. Consequently, bit 8 in MSR\_LBR\_SELECT controls filtering of the new records introduced by Intel SGX.

## 40.6 INTERACTION WITH PERFORMANCE MONITORING

### 40.6.1 IA32\_PERF\_GLOBAL\_STATUS Enhancement

On processors supporting Intel SGX, the IA32\_PERF\_GLOBAL\_STATUS MSR provides a bit indicator, known as “Anti Side-channel Interference” (ASCI) at bit position 60. If this bit is 0, the performance monitoring data in various performance monitoring counters are accumulated normally as defined by relevant architectural/microarchitectural conditions. If the ASCI bit is set, the contents in various performance monitoring counters can be affected by the direct or indirect consequence of Intel SGX protection of enclave code executing in the processor.

### 40.6.2 Performance Monitoring with Opt-in Entry

An opt-in enclave entry allows performance monitoring logic to observe the contribution of enclave code executing in the processor. Thus the contents of performance monitoring counters does not distinguish between contribution originating from enclave code or otherwise. All counters, events, precise events, etc. continue to work as defined in the IA32/Intel 64 Software Developer Manual. Consequently, bit 60 of IA32\_PERF\_GLOBAL\_STATUS MSR is not set.

### 40.6.3 Performance Monitoring with Opt-out Entry

In general, performance monitoring activities are suppressed when entering an opt-out enclave. This applies to all thread-specific, configured performance monitoring, except for the cycle-counting fixed counter, IA32\_FIXED\_CTR1 and IA32\_FIXED\_CTR2. Upon entering an opt-out enclave, IA32\_FIXED\_CTR0, IA32\_PMCx will stop accumulating counts. Additionally, if PEBS is configured to capture PEBS record for this thread, PEBS record generation will also be suppressed. Consequently, bit 60 of IA32\_PERF\_GLOBAL\_STATUS MSR is set.

Performance monitoring on the sibling thread may also be affected. Any one of IA32\_FIXED\_CTRx or IA32\_PMCx on the sibling thread configured to monitor thread-specific eventing logic with AnyThread =1 is demoted to count only MyThread while an opt-out enclave is executing on the other thread.

### 40.6.4 Enclave Exit and Performance Monitoring

When a logical processor exits an enclave, either via ENCLU[EEXIT] or via AEX, all performance monitoring activity (including PEBS) on that logical processor that was suppressed is unsuppressed.

Any counters that were demoted from AnyThread to MyThread on the sibling thread are promoted back to AnyThread.

### 40.6.5 PEBS Record Generation on Intel® SGX Instructions

All leaf functions of the ENCLS instruction report “Eventing RIP” of the ENCLS instruction if a PEBS record is generated at the end of the instruction execution. Additionally, the EGETKEY and EREPORT leaf functions of the ENCLU instruction report “Eventing RIP” of the ENCLU instruction if a PEBS record is generated at the end of the instruction execution.

If the EENTER and ERESUME leaf functions are performing an opt-in entry report “Eventing RIP” of the ENCLU instruction if a PEBS record is generated at the end of the instruction execution. On the other hand, if these leaf functions are performing an opt-out entry, then these leaf functions result in PEBS being suppressed, and no PEBS record is generated at the end of these instructions.

A PEBS record is generated if there is a PEBS event pending at the end of EEXIT (due to a counter overflowing during enclave execution or during EEXIT execution). This PEBS record contains the architectural state of the logical processor at the end of EEXIT. If the enclave was entered via an opt-in entry, then this record reports the “Eventing RIP” as the linear address of the ENCLU[EEXIT] instruction. If the enclave was entered via an opt-out entry, then the record reports the “Eventing RIP” as the linear address of the ENCLU[EENTER/ERESUME] instruction that performed the last enclave entry.

A PEBS record is generated after the AEX if there is a PEBS event pending at the end of AEX (due to a counter overflowing during enclave execution or during AEX execution). This PEBS record contains the synthetic state of the logical processor that is established at the end of AEX. For opt-in entry, this record has the EVENTING\_RIP set to the RIP saved in the SSA. For opt-out entry, the record has the EVENTING\_RIP set to the linear address of EENTER/ERESUME used for the last enclave entry.

If the enclave was entered via an opt-in entry, then this record reports the “Eventing RIP” as the linear address in the SSA of the enclave (a.k.a., the “Eventing RIP” inside the enclave). If the enclave was entered via an opt-out entry, then the record reports the “Eventing RIP” as the linear address of the ENCLU[EENTER/ERESUME] instruction that performed the last enclave entry.

A second PEBS event may be pended during the Enclave Exiting Event (EEE). If the PEBS event is taken at the end of delivery of the EEE then the “Eventing RIP” in this second PEBS record is the linear address of the AEP.

### 40.6.6 Exception-Handling on PEBS/BTS Loads/Stores after AEX

As noted in Section 18.4.9.2, recording in the BTS buffer or in the PEBS buffer may not operate properly if accesses to any of the DS save area sections cause page faults or VM exits. Such page faults or VM exits, if they occur, are delivered immediately to the OS or VMM, and generation of a BTS or PEBS record is skipped and may leave the buffers in a state where they have a partial BTS or PEBS records.

However, any events that are detected during PEBS/BTS record generation at the end of AEX and before delivering the Enclave Exiting Event (EEE) cannot be reported immediately to the OS/VMM, as an event window is not open at

the end of AEX. Consequently, fault-like events such as page faults, EPT faults, EPT mis-configuration, and accesses to APIC-access page detected on stores to the PEBS/BTS buffer are not reported, and generation of the PEBS and/or BTS record at the end of AEX is aborted (this may leave the buffers in a state where they have partial PEBS or BTS records). Trap-like events detected on stores to the PEBS/BTS buffer (such as debug traps) are pended until the next instruction boundary, where they are handled according to the architecturally defined priority. The processor continues the handling of the Enclave Exiting Event (SMI, NMI, interrupt, exception delivery, VM exit, etc.) after aborting the PEBS/BTS record generation.

#### 40.6.6.1 Other Interactions with Performance Monitoring

For opt-in entry, EENTER, ERESUME, EEXIT, and AEX are all treated as predicted far branches, and any counters that are counting such branches are incremented by 1 as a part of retirement of these instructions. Retirement of these instructions is also counted in any counters configured to count instructions retired.

For opt-out entry, execution inside an enclave is treated as a single predicted branch, and all branch-counting performance monitoring counters are incremented accordingly. Additionally, such execution is also counted as a single instruction, and all performance monitoring counters counting instructions are incremented accordingly.

Enclave entry does not affect any performance monitoring counters shared between cores.

## APPENDIX A

# VMX CAPABILITY REPORTING FACILITY

The ability of a processor to support VMX operation and related instructions is indicated by CPUID.1:ECX.VMX[bit 5] = 1. A value 1 in this bit indicates support for VMX features.

Support for specific features detailed in Chapter 27 and other VMX chapters is determined by reading values from a set of capability MSRs. These MSRs are indexed starting at MSR address 480H. VMX capability MSRs are read-only; an attempt to write them (with WRMSR) produces a general-protection exception (#GP(0)). They do not exist on processors that do not support VMX operation; an attempt to read them (with RDMSR) on such processors produces a general-protection exception (#GP(0)).

### A.1 BASIC VMX INFORMATION

The IA32\_VMX\_BASIC MSR (index 480H) consists of the following fields:

- Bits 30:0 contain the 31-bit VMCS revision identifier used by the processor. Processors that use the same VMCS revision identifier use the same size for VMCS regions (see subsequent item on bits 44:32).<sup>1</sup>
- Bit 31 is always 0.
- Bits 44:32 report the number of bytes that software should allocate for the VMXON region and any VMCS region. It is a value greater than 0 and at most 4096 (bit 44 is set if and only if bits 43:32 are clear).
- Bit 48 indicates the width of the physical addresses that may be used for the VMXON region, each VMCS, and data structures referenced by pointers in a VMCS (I/O bitmaps, virtual-APIC page, MSR areas for VMX transitions). If the bit is 0, these addresses are limited to the processor's physical-address width.<sup>2</sup> If the bit is 1, these addresses are limited to 32 bits. This bit is always 0 for processors that support Intel 64 architecture.
- If bit 49 is read as 1, the logical processor supports the dual-monitor treatment of system-management interrupts and system-management mode. See Section 32.15 for details of this treatment.
- Bits 53:50 report the memory type that should be used for the VMCS, for data structures referenced by pointers in the VMCS (I/O bitmaps, virtual-APIC page, MSR areas for VMX transitions), and for the MSEG header. If software needs to access these data structures (e.g., to modify the contents of the MSR bitmaps), it can configure the paging structures to map them into the linear-address space. If it does so, it should establish mappings that use the memory type reported bits 53:50 in this MSR.<sup>3</sup>

As of this writing, all processors that support VMX operation indicate the write-back type. The values used are given in Table A-1.

**Table A-1. Memory Types Recommended for VMCS and Related Data Structures**

| Value(s) | Field            |
|----------|------------------|
| 0        | Uncacheable (UC) |
| 1-5      | Not used         |
| 6        | Write Back (WB)  |
| 7-15     | Not used         |

- 
1. Earlier versions of this manual specified that the VMCS revision identifier was a 32-bit field in bits 31:0 of this MSR. For all processors produced prior to this change, bit 31 of this MSR was read as 0.
  2. On processors that support Intel 64 architecture, the pointer must not set bits beyond the processor's physical address width.
  3. Alternatively, software may map any of these regions or structures with the UC memory type. (This may be necessary for the MSEG header.) Doing so is discouraged unless necessary as it will cause the performance of software accesses to those structures to suffer.

- If bit 54 is read as 1, the processor reports information in the VM-exit instruction-information field on VM exits due to execution of the INS and OUTS instructions (see Section 28.2.5). This reporting is done only if this bit is read as 1.
- Bit 55 is read as 1 if any VMX controls that default to 1 may be cleared to 0. See Appendix A.2 for details. It also reports support for the VMX capability MSRs IA32\_VMX\_TRUE\_PINBASED\_CTLs, IA32\_VMX\_TRUE\_PROC-BASED\_CTLs, IA32\_VMX\_TRUE\_EXIT\_CTLs, and IA32\_VMX\_TRUE\_ENTRY\_CTLs. See Appendix A.3.1, Appendix A.3.2, Appendix A.4, and Appendix A.5 for details.
- If bit 56 is read as 1, software can use VM entry to deliver a hardware exception with or without an error code, regardless of vector (see Section 27.2.1.3).
- The values of bits 47:45 and bits 63:57 are reserved and are read as 0.

## A.2 RESERVED CONTROLS AND DEFAULT SETTINGS

As noted in Chapter 27, “VM Entries”, certain VMX controls are reserved and must be set to a specific value (0 or 1) determined by the processor. The specific value to which a reserved control must be set is its **default setting**. Software can discover the default setting of a reserved control by consulting the appropriate VMX capability MSR (see Appendix A.3 through Appendix A.5).

Future processors may define new functionality for one or more reserved controls. Such processors would allow each newly defined control to be set either to 0 or to 1. Software that does not desire a control’s new functionality should set the control to its default setting. For that reason, it is useful for software to know the default settings of the reserved controls.

Default settings partition the various controls into the following classes:

- **Always-flexible.** These have never been reserved.
- **Default0.** These are (or have been) reserved with a default setting of 0.
- **Default1.** They are (or have been) reserved with a default setting of 1.

As noted in Appendix A.1, a logical processor uses bit 55 of the IA32\_VMX\_BASIC MSR to indicate whether any of the default1 controls may be 0:

- If bit 55 of the IA32\_VMX\_BASIC MSR is read as 0, all the default1 controls are reserved and must be 1. VM entry will fail if any of these controls are 0 (see Section 27.2.1).
- If bit 55 of the IA32\_VMX\_BASIC MSR is read as 1, not all the default1 controls are reserved, and some (but not necessarily all) may be 0. The CPU supports four (4) new VMX capability MSRs: IA32\_VMX\_TRUE\_PIN-BASED\_CTLs, IA32\_VMX\_TRUE\_PROCBASED\_CTLs, IA32\_VMX\_TRUE\_EXIT\_CTLs, and IA32\_VMX\_TRUE\_ENTRY\_CTLs. See Appendix A.3 through Appendix A.5 for details. (These MSRs are not supported if bit 55 of the IA32\_VMX\_BASIC MSR is read as 0.)

## A.3 VM-EXECUTION CONTROLS

There are separate capability MSRs for the pin-based VM-execution controls, the primary processor-based VM-execution controls, the secondary processor-based VM-execution controls, and the tertiary processor-based VM-execution controls. These are described in Appendix A.3.1, Appendix A.3.2, Appendix A.3.3, and Appendix A.3.4, respectively.

### A.3.1 Pin-Based VM-Execution Controls

The IA32\_VMX\_PINBASED\_CTLs MSR (index 481H) reports on the allowed settings of **most** of the pin-based VM-execution controls (see Section 25.6.1):

- Bits 31:0 indicate the **allowed 0-settings** of these controls. VM entry allows control X (bit X of the pin-based VM-execution controls) to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0.

Exceptions are made for the pin-based VM-execution controls in the default1 class (see Appendix A.2). These are bits 1, 2, and 4; the corresponding bits of the IA32\_VMX\_PINBASED\_CTLs MSR are always read as 1. The treatment of these controls by VM entry is determined by bit 55 in the IA32\_VMX\_BASIC MSR:

- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 0, VM entry fails if any pin-based VM-execution control in the default1 class is 0.
- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, the IA32\_VMX\_TRUE\_PINBASED\_CTLs MSR (see below) reports which of the pin-based VM-execution controls in the default1 class can be 0 on VM entry.
- Bits 63:32 indicate the **allowed 1-settings** of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, the IA32\_VMX\_TRUE\_PINBASED\_CTLs MSR (index 48DH) reports on the allowed settings of **all** of the pin-based VM-execution controls:

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. There are no exceptions.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

It is necessary for software to consult only one of the capability MSRs to determine the allowed settings of the pin-based VM-execution controls:

- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 0, all information about the allowed settings of the pin-based VM-execution controls is contained in the IA32\_VMX\_PINBASED\_CTLs MSR. (The IA32\_VMX\_TRUE\_PINBASED\_CTLs MSR is not supported.)
- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, all information about the allowed settings of the pin-based VM-execution controls is contained in the IA32\_VMX\_TRUE\_PINBASED\_CTLs MSR. Assuming that software knows that the default1 class of pin-based VM-execution controls contains bits 1, 2, and 4, there is no need for software to consult the IA32\_VMX\_PINBASED\_CTLs MSR.

### A.3.2 Primary Processor-Based VM-Execution Controls

The IA32\_VMX\_PROCBASED\_CTLs MSR (index 482H) reports on the allowed settings of **most** of the primary processor-based VM-execution controls (see Section 25.6.2):

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X (bit X of the primary processor-based VM-execution controls) to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0.

Exceptions are made for the primary processor-based VM-execution controls in the default1 class (see Appendix A.2). These are bits 1, 4–6, 8, 13–16, and 26; the corresponding bits of the IA32\_VMX\_PROCBASED\_CTLs MSR are always read as 1. The treatment of these controls by VM entry is determined by bit 55 in the IA32\_VMX\_BASIC MSR:

- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 0, VM entry fails if any of the primary processor-based VM-execution controls in the default1 class is 0.
- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, the IA32\_VMX\_TRUE\_PROCBASED\_CTLs MSR (see below) reports which of the primary processor-based VM-execution controls in the default1 class can be 0 on VM entry.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, the IA32\_VMX\_TRUE\_PROCBASED\_CTLs MSR (index 48EH) reports on the allowed settings of **all** of the primary processor-based VM-execution controls:

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. There are no exceptions.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

It is necessary for software to consult only one of the capability MSRs to determine the allowed settings of the primary processor-based VM-execution controls:

- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 0, all information about the allowed settings of the primary processor-based VM-execution controls is contained in the IA32\_VMX\_PROCBASED\_CTLs MSR. (The IA32\_VMX\_TRUE\_PROCBASED\_CTLs MSR is not supported.)
- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, all information about the allowed settings of the primary processor-based VM-execution controls is contained in the IA32\_VMX\_TRUE\_PROCBASED\_CTLs MSR. Assuming that software knows that the default1 class of primary processor-based VM-execution controls contains bits 1, 4–6, 8, 13–16, and 26, there is no need for software to consult the IA32\_VMX\_PROCBASED\_CTLs MSR.

### A.3.3 Secondary Processor-Based VM-Execution Controls

The IA32\_VMX\_PROCBASED\_CTLs2 MSR (index 48BH) reports on the allowed settings of the secondary processor-based VM-execution controls (see Section 25.6.2). The following items provide details, including enforcement by VM entry:

- Bits 31:0 indicate the allowed 0-settings of these controls. These bits are always 0. This fact indicates that VM entry allows each bit of the secondary processor-based VM-execution controls to be 0 (reserved bits must be 0)
- Bits 63:32 indicate the allowed 1-settings of these controls; the 1-setting is not allowed for any reserved bit. VM entry allows control X (bit X of the secondary processor-based VM-execution controls) to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X and the “activate secondary controls” primary processor-based VM-execution control are both 1.

The IA32\_VMX\_PROCBASED\_CTLs2 MSR exists only on processors that support the 1-setting of the “activate secondary controls” VM-execution control (only if bit 63 of the IA32\_VMX\_PROCBASED\_CTLs MSR is 1).

### A.3.4 Tertiary Processor-Based VM-Execution Controls

The IA32\_VMX\_PROCBASED\_CTLs3 MSR (index 492H) reports on the allowed 1-settings of the tertiary processor-based VM-execution controls (see Section 25.6.2); the 1-setting is not allowed for any reserved bit.

VM entry allows control X (bit X of the tertiary processor-based VM-execution controls) to be 1 if bit X in the MSR is set to 1; if bit X in the MSR is cleared to 0, VM entry fails if control X and the “activate tertiary controls” primary processor-based VM-execution control are both 1.

The IA32\_VMX\_PROCBASED\_CTLs3 MSR exists only on processors that support the 1-setting of the “activate tertiary controls” VM-execution control (only if bit 49 of the IA32\_VMX\_PROCBASED\_CTLs MSR is 1).

Notice that the organization of this MSR differs from that of IA32\_VMX\_PROCBASED\_CTLs2 (Appendix A.3.3). This is because there are 64 tertiary processor-based VM-execution controls, while there were only 32 secondary processor-based VM-execution controls.

## A.4 VM-EXIT CONTROLS

There are separate capability MSRs for the primary VM-exit controls and the secondary VM-exit controls. These are described in Appendix A.4.1 and Appendix A.4.2, respectively.

### A.4.1 Primary VM-Exit Controls

The IA32\_VMX\_EXIT\_CTLs MSR (index 483H) reports on the allowed settings of **most** of the primary VM-exit controls (see Section 25.7.1):

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X (bit X of the primary VM-exit controls) to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0.

Exceptions are made for the primary VM-exit controls in the default1 class (see Appendix A.2). These are bits 0–8, 10, 11, 13, 14, 16, and 17; the corresponding bits of the IA32\_VMX\_EXIT\_CTLs MSR are always read as 1. The treatment of these controls by VM entry is determined by bit 55 in the IA32\_VMX\_BASIC MSR:

- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 0, VM entry fails if any primary VM-exit control in the default1 class is 0.
- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, the IA32\_VMX\_TRUE\_EXIT\_CTLs MSR (see below) reports which of the primary VM-exit controls in the default1 class can be 0 on VM entry.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control 32+X to be 1 if bit X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, the IA32\_VMX\_TRUE\_EXIT\_CTLs MSR (index 48FH) reports on the allowed settings of **all** of the primary VM-exit controls:

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. There are no exceptions.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

It is necessary for software to consult only one of the capability MSRs to determine the allowed settings of the primary VM-exit controls:

- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 0, all information about the allowed settings of the primary VM-exit controls is contained in the IA32\_VMX\_EXIT\_CTLs MSR. (The IA32\_VMX\_TRUE\_EXIT\_CTLs MSR is not supported.)
- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, all information about the allowed settings of the primary VM-exit controls is contained in the IA32\_VMX\_TRUE\_EXIT\_CTLs MSR. Assuming that software knows that the default1 class of primary VM-exit controls contains bits 0–8, 10, 11, 13, 14, 16, and 17, there is no need for software to consult the IA32\_VMX\_EXIT\_CTLs MSR.

## A.4.2 Secondary VM-Exit Controls

The IA32\_VMX\_EXIT\_CTLs2 MSR (index 493H) reports on the allowed 1-settings of the secondary VM-exit controls (see Section 25.7.1); the 1-setting is not allowed for any reserved bit.

VM entry allows control X (bit X of the secondary VM-exit controls) to be 1 if bit X in the MSR is set to 1; if bit X in the MSR is cleared to 0, VM entry fails if control X and the “activate secondary controls” primary VM-exit control are both 1.

The IA32\_VMX\_EXIT\_CTLs2 MSR exists only on processors that support the 1-setting of the “activate secondary controls” VM-exit control (only if bit 63 of the IA32\_VMX\_EXIT\_CTLs MSR is 1).

Notice that the organization of this MSR differs from that of IA32\_VMX\_EXIT\_CTLs (Appendix A.4.1). This is because there are 64 secondary VM-exit controls, while there were only 32 primary VM-exit controls.

## A.5 VM-ENTRY CONTROLS

The IA32\_VMX\_ENTRY\_CTLs MSR (index 484H) reports on the allowed settings of **most** of the VM-entry controls (see Section 25.8.1):

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X (bit X of the VM-entry controls) to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. Exceptions are made for the VM-entry controls in the default1 class (see Appendix A.2). These are bits 0–8 and 12; the corresponding bits of the IA32\_VMX\_ENTRY\_CTLs MSR are always read as 1. The treatment of these controls by VM entry is determined by bit 55 in the IA32\_VMX\_BASIC MSR:
  - If bit 55 in the IA32\_VMX\_BASIC MSR is read as 0, VM entry fails if any VM-entry control in the default1 class is 0.
  - If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, the IA32\_VMX\_TRUE\_ENTRY\_CTLs MSR (see below) reports which of the VM-entry controls in the default1 class can be 0 on VM entry.

- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry fails if bit X is 1 in the VM-entry controls and bit 32+X is 0 in this MSR.

If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, the IA32\_VMX\_TRUE\_ENTRY\_CTLs MSR (index 490H) reports on the allowed settings of **all** of the VM-entry controls:

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. There are no exceptions.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control 32+X to be 1 if bit X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

It is necessary for software to consult only one of the capability MSRs to determine the allowed settings of the VM-entry controls:

- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 0, all information about the allowed settings of the VM-entry controls is contained in the IA32\_VMX\_ENTRY\_CTLs MSR. (The IA32\_VMX\_TRUE\_ENTRY\_CTLs MSR is not supported.)
- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, all information about the allowed settings of the VM-entry controls is contained in the IA32\_VMX\_TRUE\_ENTRY\_CTLs MSR. Assuming that software knows that the default1 class of VM-entry controls contains bits 0–8 and 12, there is no need for software to consult the IA32\_VMX\_ENTRY\_CTLs MSR.

## A.6 MISCELLANEOUS DATA

The IA32\_VMX\_MISC MSR (index 485H) consists of the following fields:

- Bits 4:0 report a value X that specifies the relationship between the rate of the VMX-preemption timer and that of the timestamp counter (TSC). Specifically, the VMX-preemption timer (if it is active) counts down by 1 every time bit X in the TSC changes due to a TSC increment.
- If bit 5 is read as 1, VM exits store the value of IA32\_EFER.LMA into the “IA-32e mode guest” VM-entry control; see Section 28.2 for more details. This bit is read as 1 on any logical processor that supports the 1-setting of the “unrestricted guest” VM-execution control.
- Bits 8:6 report, as a bitmap, the activity states supported by the implementation:
  - Bit 6 reports (if set) the support for activity state 1 (HLT).
  - Bit 7 reports (if set) the support for activity state 2 (shutdown).
  - Bit 8 reports (if set) the support for activity state 3 (wait-for-SIPI).

If an activity state is not supported, the implementation causes a VM entry to fail if it attempts to establish that activity state. All implementations support VM entry to activity state 0 (active).

- If bit 14 is read as 1, Intel® Processor Trace (Intel PT) can be used in VMX operation. If the processor supports Intel PT but does not allow it to be used in VMX operation, execution of VMXON clears IA32\_RTIT\_CTL.TraceEn (see “VMXON—Enter VMX Operation” in Chapter 31); any attempt to write IA32\_RTIT\_CTL while in VMX operation (including VMX root operation) causes a general-protection exception.
- If bit 15 is read as 1, the RDMSR instruction can be used in system-management mode (SMM) to read the IA32\_SMBASE MSR (MSR address 9EH). See Section 32.15.6.3.
- Bits 24:16 indicate the number of CR3-target values supported by the processor. This number is a value between 0 and 256, inclusive (bit 24 is set if and only if bits 23:16 are clear).
- Bits 27:25 is used to compute the recommended maximum number of MSRs that should appear in the VM-exit MSR-store list, the VM-exit MSR-load list, or the VM-entry MSR-load list. Specifically, if the value bits 27:25 of IA32\_VMX\_MISC is N, then  $512 * (N + 1)$  is the recommended maximum number of MSRs to be included in each list. If the limit is exceeded, undefined processor behavior may result (including a machine check during the VMX transition).
- If bit 28 is read as 1, bit 2 of the IA32\_SMM\_MONITOR\_CTL can be set to 1. VMXOFF unblocks SMIs unless IA32\_SMM\_MONITOR\_CTL[bit 2] is 1 (see Section 32.14.4).
- If bit 29 is read as 1, software can use VMWRITE to write to any supported field in the VMCS; otherwise, VMWRITE cannot be used to modify VM-exit information fields.

- If bit 30 is read as 1, VM entry allows injection of a software interrupt, software exception, or privileged software exception with an instruction length of 0.
- Bits 63:32 report the 32-bit MSEG revision identifier used by the processor.
- Bits 13:9 and bit 31 are reserved and are read as 0.

## A.7 VMX-FIXED BITS IN CR0

The IA32\_VMX\_CR0\_FIXED0 MSR (index 486H) and IA32\_VMX\_CR0\_FIXED1 MSR (index 487H) indicate how bits in CR0 may be set in VMX operation. They report on bits in CR0 that are allowed to be 0 and to be 1, respectively, in VMX operation. If bit X is 1 in IA32\_VMX\_CR0\_FIXED0, then that bit of CR0 is fixed to 1 in VMX operation. Similarly, if bit X is 0 in IA32\_VMX\_CR0\_FIXED1, then that bit of CR0 is fixed to 0 in VMX operation. It is always the case that, if bit X is 1 in IA32\_VMX\_CR0\_FIXED0, then that bit is also 1 in IA32\_VMX\_CR0\_FIXED1; if bit X is 0 in IA32\_VMX\_CR0\_FIXED1, then that bit is also 0 in IA32\_VMX\_CR0\_FIXED0. Thus, each bit in CR0 is either fixed to 0 (with value 0 in both MSRs), fixed to 1 (1 in both MSRs), or flexible (0 in IA32\_VMX\_CR0\_FIXED0 and 1 in IA32\_VMX\_CR0\_FIXED1).

## A.8 VMX-FIXED BITS IN CR4

The IA32\_VMX\_CR4\_FIXED0 MSR (index 488H) and IA32\_VMX\_CR4\_FIXED1 MSR (index 489H) indicate how bits in CR4 may be set in VMX operation. They report on bits in CR4 that are allowed to be 0 and 1, respectively, in VMX operation. If bit X is 1 in IA32\_VMX\_CR4\_FIXED0, then that bit of CR4 is fixed to 1 in VMX operation. Similarly, if bit X is 0 in IA32\_VMX\_CR4\_FIXED1, then that bit of CR4 is fixed to 0 in VMX operation. It is always the case that, if bit X is 1 in IA32\_VMX\_CR4\_FIXED0, then that bit is also 1 in IA32\_VMX\_CR4\_FIXED1; if bit X is 0 in IA32\_VMX\_CR4\_FIXED1, then that bit is also 0 in IA32\_VMX\_CR4\_FIXED0. Thus, each bit in CR4 is either fixed to 0 (with value 0 in both MSRs), fixed to 1 (1 in both MSRs), or flexible (0 in IA32\_VMX\_CR4\_FIXED0 and 1 in IA32\_VMX\_CR4\_FIXED1).

## A.9 VMCS ENUMERATION

The IA32\_VMX\_VMCS\_ENUM MSR (index 48AH) provides information to assist software in enumerating fields in the VMCS.

As noted in Section 25.11.2, each field in the VMCS is associated with a 32-bit encoding which is structured as follows:

- Bits 31:15 are reserved (must be 0).
- Bits 14:13 indicate the field's width.
- Bit 12 is reserved (must be 0).
- Bits 11:10 indicate the field's type.
- Bits 9:1 is an index field that distinguishes different fields with the same width and type.
- Bit 0 indicates access type.

IA32\_VMX\_VMCS\_ENUM indicates to software the highest index value used in the encoding of any field supported by the processor:

- Bits 9:1 contain the highest index value used for any VMCS encoding.
- Bit 0 and bits 63:10 are reserved and are read as 0.

## A.10 VPID AND EPT CAPABILITIES

The IA32\_VMX\_EPT\_VPID\_CAP MSR (index 48CH) reports information about the capabilities of the logical processor with regard to virtual-processor identifiers (VPIDs, Section 29.1) and extended page tables (EPT, Section 29.3):

- If bit 0 is read as 1, the processor supports execute-only translations by EPT. This support allows software to configure EPT paging-structure entries in which bits 1:0 are clear (indicating that data accesses are not allowed) and bit 2 is set (indicating that instruction fetches are allowed).<sup>1</sup>
- Bit 6 indicates support for a page-walk length of 4.
- If bit 8 is read as 1, the logical processor allows software to configure the EPT paging-structure memory type to be uncacheable (UC); see Section 25.6.11.
- If bit 14 is read as 1, the logical processor allows software to configure the EPT paging-structure memory type to be write-back (WB).
- If bit 16 is read as 1, the logical processor allows software to configure a EPT PDE to map a 2-Mbyte page (by setting bit 7 in the EPT PDE).
- If bit 17 is read as 1, the logical processor allows software to configure a EPT PDPT to map a 1-Gbyte page (by setting bit 7 in the EPT PDPT).
- Support for the INVEPT instruction (see Chapter 31 and Section 29.4.3.1):
  - If bit 20 is read as 1, the INVEPT instruction is supported.
  - If bit 25 is read as 1, the single-context INVEPT type is supported.
  - If bit 26 is read as 1, the all-context INVEPT type is supported.
- If bit 21 is read as 1, accessed and dirty flags for EPT are supported (see Section 29.3.5).
- If bit 22 is read as 1, the processor reports advanced VM-exit information for EPT violations (see Section 28.2.1). This reporting is done only if this bit is read as 1.
- If bit 23 is read as 1, supervisor shadow-stack control is supported (see Section 29.3.3.2).
- Support for the INVVPID instruction (see Chapter 31 and Section 29.4.3.1):
  - If bit 32 is read as 1, the INVVPID instruction is supported.
  - If bit 40 is read as 1, the individual-address INVVPID type is supported.
  - If bit 41 is read as 1, the single-context INVVPID type is supported.
  - If bit 42 is read as 1, the all-context INVVPID type is supported.
  - If bit 43 is read as 1, the single-context-retaining-globals INVVPID type is supported.
- Bits 53:48 enumerate the maximum HLAT prefix size. It is expected that any processor that supports the 1-setting of the “enable HLAT” VM-execution control will enumerate this value as 1. See Section 4.5.1.
- Bits 5:1, bit 7, bits 13:9, bit 15, bits 19:18, bit 24, bits 31:27, bits 39:33, bits 47:44, and bits 63:54 are reserved and are read as 0.

The IA32\_VMX\_EPT\_VPID\_CAP MSR exists only on processors that support the 1-setting of the “activate secondary controls” VM-execution control (only if bit 63 of the IA32\_VMX\_PROCBASED\_CTLs MSR is 1) and that support either the 1-setting of the “enable EPT” VM-execution control (only if bit 33 of the IA32\_VMX\_PROCBASED\_CTLs2 MSR is 1) or the 1-setting of the “enable VPID” VM-execution control (only if bit 37 of the IA32\_VMX\_PROCBASED\_CTLs2 MSR is 1).

---

1. If the “mode-based execute control for EPT” VM-execution control is 1, setting bit 0 indicates also that software may also configure EPT paging-structure entries in which bits 1:0 are both clear and in which bit 10 is set (indicating a translation that can be used to fetch instructions from a supervisor-mode linear address or a user-mode linear address).

## A.11 VM FUNCTIONS

The IA32\_VMX\_VMFUNC MSR (index 491H) reports on the allowed settings of the VM-function controls (see Section 25.6.14). VM entry allows bit X of the VM-function controls to be 1 if bit X in the MSR is set to 1; if bit X in the MSR is cleared to 0, VM entry fails if bit X of the VM-function controls, the “activate secondary controls” primary processor-based VM-execution control, and the “enable VM functions” secondary processor-based VM-execution control are all 1.

The IA32\_VMX\_VMFUNC MSR exists only on processors that support the 1-setting of the “activate secondary controls” VM-execution control (only if bit 63 of the IA32\_VMX\_PROCBASED\_CTLs MSR is 1) and the 1-setting of the “enable VM functions” secondary processor-based VM-execution control (only if bit 45 of the IA32\_VMX\_PROCBASED\_CTLs2 MSR is 1).

VMX CAPABILITY REPORTING FACILITY

## APPENDIX B FIELD ENCODING IN VMCS

Every component of the VMCS is encoded by a 32-bit field that can be used by VMREAD and VMWRITE. Section 25.11.2 describes the structure of the encoding space (the meanings of the bits in each 32-bit encoding).

This appendix enumerates all fields in the VMCS and their encodings. Fields are grouped by width (16-bit, 32-bit, etc.) and type (guest-state, host-state, etc.).

### B.1 16-BIT FIELDS

A value of 0 in bits 14:13 of an encoding indicates a 16-bit field. Only guest-state areas and the host-state area contain 16-bit fields. As noted in Section 25.11.2, each 16-bit field allows only full access, meaning that bit 0 of its encoding is 0. Each such encoding is thus an even number.

#### B.1.1 16-Bit Control Fields

A value of 0 in bits 11:10 of an encoding indicates a control field. These fields are distinguished by their index value in bits 9:1. Table B-1 enumerates the 16-bit control fields.

**Table B-1. Encoding for 16-Bit Control Fields (0000\_00xx\_xxxx\_xxx0B)**

| Field Name                                        | Index      | Encoding  |
|---------------------------------------------------|------------|-----------|
| Virtual-processor identifier (VPID) <sup>1</sup>  | 000000000B | 00000000H |
| Posted-interrupt notification vector <sup>2</sup> | 000000001B | 00000002H |
| EPTP index <sup>3</sup>                           | 000000010B | 00000004H |
| HLAT prefix size <sup>4</sup>                     | 000000011B | 00000006H |
| Last PID-pointer index <sup>5</sup>               | 000000100B | 00000008H |

**NOTES:**

1. This field exists only on processors that support the 1-setting of the “enable VPID” VM-execution control.
2. This field exists only on processors that support the 1-setting of the “process posted interrupts” VM-execution control.
3. This field exists only on processors that support the 1-setting of the “EPT-violation #VE” VM-execution control.
4. This field exists only on processors that support the 1-setting of the “enable HLAT” VM-execution control.
5. This field exists only on processors that support the 1-setting of the “IPI virtualization” VM-execution control.

#### B.1.2 16-Bit Guest-State Fields

A value of 2 in bits 11:10 of an encoding indicates a field in the guest-state area. These fields are distinguished by their index value in bits 9:1. Table B-2 enumerates 16-bit guest-state fields.

**Table B-2. Encodings for 16-Bit Guest-State Fields (0000\_10xx\_xxxx\_xxx0B)**

| Field Name        | Index      | Encoding  |
|-------------------|------------|-----------|
| Guest ES selector | 000000000B | 00000800H |
| Guest CS selector | 000000001B | 00000802H |
| Guest SS selector | 000000010B | 00000804H |
| Guest DS selector | 000000011B | 00000806H |
| Guest FS selector | 000000100B | 00000808H |

**Table B-2. Encodings for 16-Bit Guest-State Fields (0000\_10xx\_xxxx\_xxx0B) (Contd.)**

| Field Name                          | Index      | Encoding  |
|-------------------------------------|------------|-----------|
| Guest GS selector                   | 000000101B | 0000080AH |
| Guest LDTR selector                 | 000000110B | 0000080CH |
| Guest TR selector                   | 000000111B | 0000080EH |
| Guest interrupt status <sup>1</sup> | 000001000B | 00000810H |
| PML index <sup>2</sup>              | 000001001B | 00000812H |
| Guest UINV <sup>3</sup>             | 000001010B | 00000814H |

**NOTES:**

1. This field exists only on processors that support the 1-setting of the “virtual-interrupt delivery” VM-execution control.
2. This field exists only on processors that support the 1-setting of the “enable PML” VM-execution control.
3. This field exists only on processors that support the 1-setting of either the “clear UINV” VM-exit control or the “load UINV” VM-entry control.

**B.1.3 16-Bit Host-State Fields**

A value of 3 in bits 11:10 of an encoding indicates a field in the host-state area. These fields are distinguished by their index value in bits 9:1. Table B-3 enumerates the 16-bit host-state fields.

**Table B-3. Encodings for 16-Bit Host-State Fields (0000\_11xx\_xxxx\_xxx0B)**

| Field Name       | Index      | Encoding  |
|------------------|------------|-----------|
| Host ES selector | 000000000B | 00000C00H |
| Host CS selector | 000000001B | 00000C02H |
| Host SS selector | 000000010B | 00000C04H |
| Host DS selector | 000000011B | 00000C06H |
| Host FS selector | 000000100B | 00000C08H |
| Host GS selector | 000000101B | 00000C0AH |
| Host TR selector | 000000110B | 00000C0CH |

**B.2 64-BIT FIELDS**

A value of 1 in bits 14:13 of an encoding indicates a 64-bit field. There are 64-bit fields only for controls and for guest state. As noted in Section 25.11.2, every 64-bit field has two encodings, which differ on bit 0, the access type. Thus, each such field has an even encoding for full access and an odd encoding for high access.

**B.2.1 64-Bit Control Fields**

A value of 0 in bits 11:10 of an encoding indicates a control field. These fields are distinguished by their index value in bits 9:1. Table B-4 enumerates the 64-bit control fields.

**Table B-4. Encodings for 64-Bit Control Fields (0010\_00xx\_xxxx\_xxxAb)**

| Field Name                     | Index      | Encoding  |
|--------------------------------|------------|-----------|
| Address of I/O bitmap A (full) | 000000000B | 00002000H |
| Address of I/O bitmap A (high) |            | 00002001H |
| Address of I/O bitmap B (full) | 000000001B | 00002002H |
| Address of I/O bitmap B (high) |            | 00002003H |

**Table B-4. Encodings for 64-Bit Control Fields (0010\_00xx\_xxxx\_xxxAb) (Contd.)**

| Field Name                                              | Index      | Encoding  |
|---------------------------------------------------------|------------|-----------|
| Address of MSR bitmaps (full) <sup>1</sup>              | 000000010B | 00002004H |
| Address of MSR bitmaps (high) <sup>1</sup>              |            | 00002005H |
| VM-exit MSR-store address (full)                        | 000000011B | 00002006H |
| VM-exit MSR-store address (high)                        |            | 00002007H |
| VM-exit MSR-load address (full)                         | 000000100B | 00002008H |
| VM-exit MSR-load address (high)                         |            | 00002009H |
| VM-entry MSR-load address (full)                        | 000000101B | 0000200AH |
| VM-entry MSR-load address (high)                        |            | 0000200BH |
| Executive-VMCS pointer (full)                           | 000000110B | 0000200CH |
| Executive-VMCS pointer (high)                           |            | 0000200DH |
| PML address (full) <sup>2</sup>                         | 000000111B | 0000200EH |
| PML address (high) <sup>2</sup>                         |            | 0000200FH |
| TSC offset (full)                                       | 000001000B | 00002010H |
| TSC offset (high)                                       |            | 00002011H |
| Virtual-APIC address (full) <sup>3</sup>                | 000001001B | 00002012H |
| Virtual-APIC address (high) <sup>3</sup>                |            | 00002013H |
| APIC-access address (full) <sup>4</sup>                 | 000001010B | 00002014H |
| APIC-access address (high) <sup>4</sup>                 |            | 00002015H |
| Posted-interrupt descriptor address (full) <sup>5</sup> | 000001011B | 00002016H |
| Posted-interrupt descriptor address (high) <sup>5</sup> |            | 00002017H |
| VM-function controls (full) <sup>6</sup>                | 000001100B | 00002018H |
| VM-function controls (high) <sup>6</sup>                |            | 00002019H |
| EPT pointer (EPTP; full) <sup>7</sup>                   | 000001101B | 0000201AH |
| EPT pointer (EPTP; high) <sup>7</sup>                   |            | 0000201BH |
| EOI-exit bitmap 0 (EOI_EXIT0; full) <sup>8</sup>        | 000001110B | 0000201CH |
| EOI-exit bitmap 0 (EOI_EXIT0; high) <sup>8</sup>        |            | 0000201DH |
| EOI-exit bitmap 1 (EOI_EXIT1; full) <sup>8</sup>        | 000001111B | 0000201EH |
| EOI-exit bitmap 1 (EOI_EXIT1; high) <sup>8</sup>        |            | 0000201FH |
| EOI-exit bitmap 2 (EOI_EXIT2; full) <sup>8</sup>        | 000010000B | 00002020H |
| EOI-exit bitmap 2 (EOI_EXIT2; high) <sup>8</sup>        |            | 00002021H |
| EOI-exit bitmap 3 (EOI_EXIT3; full) <sup>8</sup>        | 000010001B | 00002022H |
| EOI-exit bitmap 3 (EOI_EXIT3; high) <sup>8</sup>        |            | 00002023H |
| EPTP-list address (full) <sup>9</sup>                   | 000010010B | 00002024H |
| EPTP-list address (high) <sup>9</sup>                   |            | 00002025H |
| VMREAD-bitmap address (full) <sup>10</sup>              | 000010011B | 00002026H |
| VMREAD-bitmap address (high) <sup>10</sup>              |            | 00002027H |
| VMWRITE-bitmap address (full) <sup>10</sup>             | 000010100B | 00002028H |
| VMWRITE-bitmap address (high) <sup>10</sup>             |            | 00002029H |

**Table B-4. Encodings for 64-Bit Control Fields (0010\_00xx\_xxxx\_xxxAb) (Contd.)**

| Field Name                                                                        | Index      | Encoding  |
|-----------------------------------------------------------------------------------|------------|-----------|
| Virtualization-exception information address (full) <sup>11</sup>                 | 000010101B | 0000202AH |
| Virtualization-exception information address (high) <sup>11</sup>                 |            | 0000202BH |
| XSS-exiting bitmap (full) <sup>12</sup>                                           | 000010110B | 0000202CH |
| XSS-exiting bitmap (high) <sup>12</sup>                                           |            | 0000202DH |
| ENCLS-exiting bitmap (full) <sup>13</sup>                                         | 000010111B | 0000202EH |
| ENCLS-exiting bitmap (high) <sup>13</sup>                                         |            | 0000202FH |
| Sub-page-permission-table pointer (full) <sup>14</sup>                            | 000011000B | 00002030H |
| Sub-page-permission-table pointer (high) <sup>14</sup>                            |            | 00002031H |
| TSC multiplier (full) <sup>15</sup>                                               | 000011001B | 00002032H |
| TSC multiplier (high) <sup>15</sup>                                               |            | 00002033H |

**NOTES:**

1. This field exists only on processors that support the 1-setting of the “use MSR bitmaps” VM-execution control.
2. This field exists only on processors that support the 1-setting of the “enable PML” VM-execution control.
3. This field exists only on processors that support the 1-setting of the “use TPR shadow” VM-execution control.
4. This field exists only on processors that support the 1-setting of the “virtualize APIC accesses” VM-execution control.
5. This field exists only on processors that support the 1-setting of the “process posted interrupts” VM-execution control.
6. This field exists only on processors that support the 1-setting of the “enable VM functions” VM-execution control.
7. This field exists only on processors that support the 1-setting of the “enable EPT” VM-execution control.
8. This field exists only on processors that support the 1-setting of the “virtual-interrupt delivery” VM-execution control.
9. This field exists only on processors that support the 1-setting of the “EPTP switching” VM-function control.
10. This field exists only on processors that support the 1-setting of the “VMCS shadowing” VM-execution control.
11. This field exists only on processors that support the 1-setting of the “EPT-violation #VE” VM-execution control.
12. This field exists only on processors that support the 1-setting of the “enable XSAVES/XRSTORS” VM-execution control.

13. This field exists only on processors that support the 1-setting of the "enable ENCLS exiting" VM-execution control.
14. This field exists only on processors that support the 1-setting of the "sub-page write permissions for EPT" VM-execution control.
15. This field exists only on processors that support the 1-setting of the "use TSC scaling" VM-execution control.
16. This field exists only on processors that support the 1-setting of the "activate tertiary controls" VM-execution control.
17. This field exists only on processors that support the 1-setting of the "enable ENCLV exiting" VM-execution control.
18. This field exists only on processors that support the 1-setting of the "PASID translation" VM-execution control.
19. This field exists only on processors that support the 1-setting of the "shared-EPTP" VM-execution control.
20. This field exists only on processors that support the 1-setting of the "enable PCONFIG" VM-execution control.
21. This field exists only on processors that support the 1-setting of the "enable HLAT" VM-execution control.
22. This field exists only on processors that support the 1-setting of the "IPI virtualization" VM-execution control.
23. This field exists only on processors that support the 1-setting of the "activate secondary controls" VM-exit control.

## B.2.2 64-Bit Read-Only Data Field

A value of 1 in bits 11:10 of an encoding indicates a read-only data field. These fields are distinguished by their index value in bits 9:1. There is only one such 64-bit field as given in Table B-5.(As with other 64-bit fields, this one has two encodings.)

**Table B-5. Encodings for 64-Bit Read-Only Data Field (0010\_01xx\_xxxx\_xxxAb)**

| Field Name                                 | Index     | Encoding  |
|--------------------------------------------|-----------|-----------|
| Guest-physical address (full) <sup>1</sup> |           | 00002400H |
| Guest-physical address (high) <sup>1</sup> | 00000000B | 00002401H |

**NOTES:**

1. This field exists only on processors that support the 1-setting of the "enable EPT" VM-execution control.

## B.2.3 64-Bit Guest-State Fields

A value of 2 in bits 11:10 of an encoding indicates a field in the guest-state area. These fields are distinguished by their index value in bits 9:1. Table B-6 enumerates the 64-bit guest-state fields.

**Table B-6. Encodings for 64-Bit Guest-State Fields (0010\_10xx\_xxxx\_xxxAb)**

| Field Name                                      | Index      | Encoding  |
|-------------------------------------------------|------------|-----------|
| VMCS link pointer (full)                        |            | 00002800H |
| VMCS link pointer (high)                        | 00000000B  | 00002801H |
| Guest IA32_DEBUGCTL (full)                      |            | 00002802H |
| Guest IA32_DEBUGCTL (high)                      | 000000001B | 00002803H |
| Guest IA32_PAT (full) <sup>1</sup>              |            | 00002804H |
| Guest IA32_PAT (high) <sup>1</sup>              | 000000010B | 00002805H |
| Guest IA32_EFER (full) <sup>2</sup>             |            | 00002806H |
| Guest IA32_EFER (high) <sup>2</sup>             | 000000011B | 00002807H |
| Guest IA32_PERF_GLOBAL_CTRL (full) <sup>3</sup> |            | 00002808H |
| Guest IA32_PERF_GLOBAL_CTRL (high) <sup>3</sup> | 000000100B | 00002809H |
| Guest PDPTE0 (full) <sup>4</sup>                |            | 0000280AH |
| Guest PDPTE0 (high) <sup>4</sup>                | 000000101B | 0000280BH |

**Table B-6. Encodings for 64-Bit Guest-State Fields (0010\_10xx\_xxxx\_xxxAb) (Contd.)**

| Field Name                              | Index      | Encoding  |
|-----------------------------------------|------------|-----------|
| Guest PDPTE1 (full) <sup>4</sup>        | 000000110B | 0000280CH |
| Guest PDPTE1 (high) <sup>4</sup>        |            | 0000280DH |
| Guest PDPTE2 (full) <sup>4</sup>        | 000000111B | 0000280EH |
| Guest PDPTE2 (high) <sup>4</sup>        |            | 0000280FH |
| Guest PDPTE3 (full) <sup>4</sup>        | 000001000B | 00002810H |
| Guest PDPTE3 (high) <sup>4</sup>        |            | 00002811H |
| Guest IA32_BNDCFGS (full) <sup>5</sup>  | 000001001B | 00002812H |
| Guest IA32_BNDCFGS (high) <sup>5</sup>  |            | 00002813H |
| Guest IA32_RTIT_CTL (full) <sup>6</sup> | 000001010B | 00002814H |
| Guest IA32_RTIT_CTL (high) <sup>6</sup> |            | 00002815H |
| Guest IA32_LBR_CTL (full) <sup>7</sup>  | 000001011B | 00002816H |
| Guest IA32_LBR_CTL (high) <sup>7</sup>  |            | 00002817H |
| Guest IA32_PKRS (full) <sup>8</sup>     | 000001100B | 00002818H |
| Guest IA32_PKRS (high) <sup>8</sup>     |            | 00002819H |

**NOTES:**

1. This field exists only on processors that support either the 1-setting of the “load IA32\_PAT” VM-entry control or that of the “save IA32\_PAT” VM-exit control.
2. This field exists only on processors that support either the 1-setting of the “load IA32\_EFER” VM-entry control or that of the “save IA32\_EFER” VM-exit control.
3. This field exists only on processors that support the 1-setting of the “load IA32\_PERF\_GLOBAL\_CTRL” VM-entry control.
4. This field exists only on processors that support the 1-setting of the “enable EPT” VM-execution control.
5. This field exists only on processors that support either the 1-setting of the “load IA32\_BNDCFGS” VM-entry control or that of the “clear IA32\_BNDCFGS” VM-exit control.
6. This field exists only on processors that support either the 1-setting of the “load IA32\_RTIT\_CTL” VM-entry control or that of the “clear IA32\_RTIT\_CTL” VM-exit control.
7. This field exists only on processors that support either the 1-setting of the “load IA32\_LBR\_CTL” VM-entry control or that of the “clear IA32\_LBR\_CTL” VM-exit control.
8. This field exists only on processors that support the 1-setting of the “load PKRS” VM-entry control.

**B.2.4 64-Bit Host-State Fields**

A value of 3 in bits 11:10 of an encoding indicates a field in the host-state area. These fields are distinguished by their index value in bits 9:1. Table B-7 enumerates the 64-bit control fields.

**Table B-7. Encodings for 64-Bit Host-State Fields (0010\_11xx\_xxxx\_xxxAb)**

| Field Name                                     | Index      | Encoding  |
|------------------------------------------------|------------|-----------|
| Host IA32_PAT (full) <sup>1</sup>              | 000000000B | 00002C00H |
| Host IA32_PAT (high) <sup>1</sup>              |            | 00002C01H |

**NOTES:**

1. This field exists only on processors that support the 1-setting of the “load IA32\_PAT” VM-exit control.
2. This field exists only on processors that support the 1-setting of the “load IA32\_EFER” VM-exit control.
3. This field exists only on processors that support the 1-setting of the “load IA32\_PERF\_GLOBAL\_CTRL” VM-exit control.
4. This field exists only on processors that support the 1-setting of the “load PKRS” VM-exit control.

## B.3 32-BIT FIELDS

A value of 2 in bits 14:13 of an encoding indicates a 32-bit field. As noted in Section 25.11.2, each 32-bit field allows only full access, meaning that bit 0 of its encoding is 0. Each such encoding is thus an even number.

### B.3.1 32-Bit Control Fields

A value of 0 in bits 11:10 of an encoding indicates a control field. These fields are distinguished by their index value in bits 9:1. Table B-8 enumerates the 32-bit control fields.

**Table B-8. Encodings for 32-Bit Control Fields (0100\_00xx\_xxxx\_xxx0B)**

| Field Name                                                   | Index      | Encoding  |
|--------------------------------------------------------------|------------|-----------|
| Pin-based VM-execution controls                              | 000000000B | 00004000H |
| Primary processor-based VM-execution controls                | 000000001B | 00004002H |
| Exception bitmap                                             | 000000010B | 00004004H |
| Page-fault error-code mask                                   | 000000011B | 00004006H |
| Page-fault error-code match                                  | 000000100B | 00004008H |
| CR3-target count                                             | 000000101B | 0000400AH |
| Primary VM-exit controls                                     | 000000110B | 0000400CH |
| VM-exit MSR-store count                                      | 000000111B | 0000400EH |
| VM-exit MSR-load count                                       | 000001000B | 00004010H |
| VM-entry controls                                            | 000001001B | 00004012H |
| VM-entry MSR-load count                                      | 000001010B | 00004014H |
| VM-entry interruption-information field                      | 000001011B | 00004016H |
| VM-entry exception error code                                | 000001100B | 00004018H |
| VM-entry instruction length                                  | 000001101B | 0000401AH |
| TPR threshold <sup>1</sup>                                   | 000001110B | 0000401CH |
| Secondary processor-based VM-execution controls <sup>2</sup> | 000001111B | 0000401EH |
| PLE_Gap <sup>3</sup>                                         | 000010000B | 00004020H |
| PLE_Window <sup>3</sup>                                      | 000010001B | 00004022H |
| Instruction-timeout control <sup>4</sup>                     | 000010010B | 00004024H |

**NOTES:**

1. This field exists only on processors that support the 1-setting of the “use TPR shadow” VM-execution control.

2. This field exists only on processors that support the 1-setting of the “activate secondary controls” VM-execution control.
3. This field exists only on processors that support the 1-setting of the “PAUSE-loop exiting” VM-execution control.
4. This field exists only on processors that support the 1-setting of the “instruction timeout” VM-execution control.

### B.3.2 32-Bit Read-Only Data Fields

A value of 1 in bits 11:10 of an encoding indicates a read-only data field. These fields are distinguished by their index value in bits 9:1. Table B-9 enumerates the 32-bit read-only data fields.

**Table B-9. Encodings for 32-Bit Read-Only Data Fields (0100\_01xx\_xxxx\_xxx0B)**

| Field Name                       | Index      | Encoding  |
|----------------------------------|------------|-----------|
| VM-instruction error             | 000000000B | 00004400H |
| Exit reason                      | 000000001B | 00004402H |
| VM-exit interruption information | 000000010B | 00004404H |
| VM-exit interruption error code  | 000000011B | 00004406H |
| IDT-vectoring information field  | 000000100B | 00004408H |
| IDT-vectoring error code         | 000000101B | 0000440AH |
| VM-exit instruction length       | 000000110B | 0000440CH |
| VM-exit instruction information  | 000000111B | 0000440EH |

### B.3.3 32-Bit Guest-State Fields

A value of 2 in bits 11:10 of an encoding indicates a field in the guest-state area. These fields are distinguished by their index value in bits 9:1. Table B-10 enumerates the 32-bit guest-state fields.

**Table B-10. Encodings for 32-Bit Guest-State Fields (0100\_10xx\_xxxx\_xxx0B)**

| Field Name               | Index      | Encoding  |
|--------------------------|------------|-----------|
| Guest ES limit           | 000000000B | 00004800H |
| Guest CS limit           | 000000001B | 00004802H |
| Guest SS limit           | 000000010B | 00004804H |
| Guest DS limit           | 000000011B | 00004806H |
| Guest FS limit           | 000000100B | 00004808H |
| Guest GS limit           | 000000101B | 0000480AH |
| Guest LDTR limit         | 000000110B | 0000480CH |
| Guest TR limit           | 000000111B | 0000480EH |
| Guest GDTR limit         | 000001000B | 00004810H |
| Guest IDTR limit         | 000001001B | 00004812H |
| Guest ES access rights   | 000001010B | 00004814H |
| Guest CS access rights   | 000001011B | 00004816H |
| Guest SS access rights   | 000001100B | 00004818H |
| Guest DS access rights   | 000001101B | 0000481AH |
| Guest FS access rights   | 000001110B | 0000481CH |
| Guest GS access rights   | 000001111B | 0000481EH |
| Guest LDTR access rights | 000010000B | 00004820H |

**Table B-10. Encodings for 32-Bit Guest-State Fields (0100\_10xx\_xxxx\_xxx0B) (Contd.)**

| Field Name                              | Index      | Encoding  |
|-----------------------------------------|------------|-----------|
| Guest TR access rights                  | 000010001B | 00004822H |
| Guest interruptibility state            | 000010010B | 00004824H |
| Guest activity state                    | 000010011B | 00004826H |
| Guest SMBASE                            | 000010100B | 00004828H |
| Guest IA32_SYSENTER_CS                  | 000010101B | 0000482AH |
| VMX-preemption timer value <sup>1</sup> | 000010111B | 0000482EH |

**NOTES:**

1. This field exists only on processors that support the 1-setting of the “activate VMX-preemption timer” VM-execution control.

The limit fields for GDTR and IDTR are defined to be 32 bits in width even though these fields are only 16-bits wide in the Intel 64 and IA-32 architectures. VM entry ensures that the high 16 bits of both these fields are cleared to 0.

### B.3.4 32-Bit Host-State Field

A value of 3 in bits 11:10 of an encoding indicates a field in the host-state area. There is only one such 32-bit field as given in Table B-11.

**Table B-11. Encoding for 32-Bit Host-State Field (0100\_11xx\_xxxx\_xxx0B)**

| Field Name            | Index      | Encoding  |
|-----------------------|------------|-----------|
| Host IA32_SYSENTER_CS | 000000000B | 00004C00H |

## B.4 NATURAL-WIDTH FIELDS

A value of 3 in bits 14:13 of an encoding indicates a natural-width field. As noted in Section 25.11.2, each of these fields allows only full access, meaning that bit 0 of its encoding is 0. Each such encoding is thus an even number.

### B.4.1 Natural-Width Control Fields

A value of 0 in bits 11:10 of an encoding indicates a control field. These fields are distinguished by their index value in bits 9:1. Table B-12 enumerates the natural-width control fields.

**Table B-12. Encodings for Natural-Width Control Fields (0110\_00xx\_xxxx\_xxx0B)**

| Field Name                      | Index       | Encoding  |
|---------------------------------|-------------|-----------|
| CRO guest/host mask             | 0000000000B | 00006000H |
| CR4 guest/host mask             | 0000000001B | 00006002H |
| CRO read shadow                 | 0000000010B | 00006004H |
| CR4 read shadow                 | 0000000011B | 00006006H |
| CR3-target value 0              | 000000100B  | 00006008H |
| CR3-target value 1              | 000000101B  | 0000600AH |
| CR3-target value 2              | 000000110B  | 0000600CH |
| CR3-target value 3 <sup>1</sup> | 000000111B  | 0000600EH |

**NOTES:**

1. If a future implementation supports more than 4 CR3-target values, they will be encoded consecutively following the 4 encodings given here.

**B.4.2 Natural-Width Read-Only Data Fields**

A value of 1 in bits 11:10 of an encoding indicates a read-only data field. These fields are distinguished by their index value in bits 9:1. Table B-13 enumerates the natural-width read-only data fields.

**Table B-13. Encodings for Natural-Width Read-Only Data Fields (0110\_01xx\_xxxx\_xxx0B)**

| Field Name           | Index      | Encoding  |
|----------------------|------------|-----------|
| Exit qualification   | 000000000B | 00006400H |
| I/O RCX              | 000000001B | 00006402H |
| I/O RSI              | 000000010B | 00006404H |
| I/O RDI              | 000000011B | 00006406H |
| I/O RIP              | 000000100B | 00006408H |
| Guest-linear address | 000000101B | 0000640AH |

**B.4.3 Natural-Width Guest-State Fields**

A value of 2 in bits 11:10 of an encoding indicates a field in the guest-state area. These fields are distinguished by their index value in bits 9:1. Table B-14 enumerates the natural-width guest-state fields.

**Table B-14. Encodings for Natural-Width Guest-State Fields (0110\_10xx\_xxxx\_xxx0B)**

| Field Name                     | Index      | Encoding  |
|--------------------------------|------------|-----------|
| Guest CR0                      | 000000000B | 00006800H |
| Guest CR3                      | 000000001B | 00006802H |
| Guest CR4                      | 000000010B | 00006804H |
| Guest ES base                  | 000000011B | 00006806H |
| Guest CS base                  | 000000100B | 00006808H |
| Guest SS base                  | 000000101B | 0000680AH |
| Guest DS base                  | 000000110B | 0000680CH |
| Guest FS base                  | 000000111B | 0000680EH |
| Guest GS base                  | 000001000B | 00006810H |
| Guest LDTR base                | 000001001B | 00006812H |
| Guest TR base                  | 000001010B | 00006814H |
| Guest GDTR base                | 000001011B | 00006816H |
| Guest IDTR base                | 000001100B | 00006818H |
| Guest DR7                      | 000001101B | 0000681AH |
| Guest RSP                      | 000001110B | 0000681CH |
| Guest RIP                      | 000001111B | 0000681EH |
| Guest RFLAGS                   | 000010000B | 00006820H |
| Guest pending debug exceptions | 000010001B | 00006822H |

**Table B-14. Encodings for Natural-Width Guest-State Fields (0110\_10xx\_xxxx\_xxx0B) (Contd.)**

| Field Name                                       | Index      | Encoding  |
|--------------------------------------------------|------------|-----------|
| Guest IA32_SYSENTER_ESP                          | 000010010B | 00006824H |
| Guest IA32_SYSENTER_EIP                          | 000010011B | 00006826H |
| Guest IA32_S_CET <sup>1</sup>                    | 000010100B | 00006828H |
| Guest SSP <sup>1</sup>                           | 000010101B | 0000682AH |
| Guest IA32_INTERRUPT_SSP_TABLE_ADDR <sup>1</sup> | 000010110B | 0000682CH |

**NOTES:**

1. This field is supported only on processors that support the 1-setting of the “load CET state” VM-entry control.

The base-address fields for ES, CS, SS, and DS in the guest-state area are defined to be natural-width (with 64 bits on processors supporting Intel 64 architecture) even though these fields are only 32-bits wide in the Intel 64 architecture. VM entry ensures that the high 32 bits of these fields are cleared to 0.

#### B.4.4 Natural-Width Host-State Fields

A value of 3 in bits 11:10 of an encoding indicates a field in the host-state area. These fields are distinguished by their index value in bits 9:1. Table B-15 enumerates the natural-width host-state fields.

**Table B-15. Encodings for Natural-Width Host-State Fields (0110\_11xx\_xxxx\_xxx0B)**

| Field Name                                      | Index      | Encoding  |
|-------------------------------------------------|------------|-----------|
| Host CR0                                        | 000000000B | 00006C00H |
| Host CR3                                        | 000000001B | 00006C02H |
| Host CR4                                        | 000000010B | 00006C04H |
| Host FS base                                    | 000000011B | 00006C06H |
| Host GS base                                    | 000000100B | 00006C08H |
| Host TR base                                    | 000000101B | 00006C0AH |
| Host GDTR base                                  | 000000110B | 00006C0CH |
| Host IDTR base                                  | 000000111B | 00006C0EH |
| Host IA32_SYSENTER_ESP                          | 000001000B | 00006C10H |
| Host IA32_SYSENTER_EIP                          | 000001001B | 00006C12H |
| Host RSP                                        | 000001010B | 00006C14H |
| Host RIP                                        | 000001011B | 00006C16H |
| Host IA32_S_CET <sup>1</sup>                    | 000001100B | 00006C18H |
| Host SSP <sup>1</sup>                           | 000001101B | 00006C1AH |
| Host IA32_INTERRUPT_SSP_TABLE_ADDR <sup>1</sup> | 000001110B | 00006C1CH |

**NOTES:**

1. This field is supported only on processors that support the 1-setting of the “load CET state” VM-exit control.

## FIELD ENCODING IN VMCS

## APPENDIX C

# VMX BASIC EXIT REASONS

---

Every VM exit writes a 32-bit exit reason to the VMCS (see Section 25.9.1). Certain VM-entry failures also do this (see Section 27.8). The low 16 bits of the exit-reason field form the basic exit reason which provides basic information about the cause of the VM exit or VM-entry failure.

Table C-1 lists values for basic exit reasons and explains their meaning. Entries apply to VM exits, unless otherwise noted.

**Table C-1. Basic Exit Reasons**

| Basic Exit Reason | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                 | <b>Exception or non-maskable interrupt (NMI).</b> Either:<br>1: Guest software caused an exception and the bit in the exception bitmap associated with exception's vector was 1. This case includes executions of BOUND that cause #BR, executions of INT1 (they cause #DB), executions of INT3 (they cause #BP), executions of INTO that cause #OF, and executions of UD0, UD1, and UD2 (they cause #UD).<br>2: An NMI was delivered to the logical processor and the "NMI exiting" VM-execution control was 1. |
| 1                 | <b>External interrupt.</b> An external interrupt arrived and the "external-interrupt exiting" VM-execution control was 1.                                                                                                                                                                                                                                                                                                                                                                                        |
| 2                 | <b>Triple fault.</b> The logical processor encountered an exception while attempting to call the double-fault handler and that exception did not itself cause a VM exit due to the exception bitmap.                                                                                                                                                                                                                                                                                                             |
| 3                 | <b>INIT signal.</b> An INIT signal arrived                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 4                 | <b>Start-up IPI (SIPI).</b> A SIPI arrived while the logical processor was in the "wait-for-SIPI" state.                                                                                                                                                                                                                                                                                                                                                                                                         |
| 5                 | <b>I/O system-management interrupt (SMI).</b> An SMI arrived immediately after retirement of an I/O instruction and caused an SMM VM exit (see Section 32.15.2).                                                                                                                                                                                                                                                                                                                                                 |
| 6                 | <b>Other SMI.</b> An SMI arrived and caused an SMM VM exit (see Section 32.15.2) but not immediately after retirement of an I/O instruction.                                                                                                                                                                                                                                                                                                                                                                     |
| 7                 | <b>Interrupt window.</b> At the beginning of an instruction, RFLAGS.IF was 1; events were not blocked by STI or by MOV SS; and the "interrupt-window exiting" VM-execution control was 1.                                                                                                                                                                                                                                                                                                                        |
| 8                 | <b>NMI window.</b> At the beginning of an instruction, there was no virtual-NMI blocking; events were not blocked by MOV SS; and the "NMI-window exiting" VM-execution control was 1.                                                                                                                                                                                                                                                                                                                            |
| 9                 | <b>Task switch.</b> Guest software attempted a task switch.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 10                | <b>CPUID.</b> Guest software attempted to execute CPUID.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 11                | <b>GETSEC.</b> Guest software attempted to execute GETSEC.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 12                | <b>HLT.</b> Guest software attempted to execute HLT and the "HLT exiting" VM-execution control was 1.                                                                                                                                                                                                                                                                                                                                                                                                            |
| 13                | <b>INVD.</b> Guest software attempted to execute INVD.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 14                | <b>INVLPG.</b> Guest software attempted to execute INVLPG and the "INVLPG exiting" VM-execution control was 1.                                                                                                                                                                                                                                                                                                                                                                                                   |
| 15                | <b>RDPMC.</b> Guest software attempted to execute RDPMC and the "RDPMC exiting" VM-execution control was 1.                                                                                                                                                                                                                                                                                                                                                                                                      |
| 16                | <b>RDTSC.</b> Guest software attempted to execute RDTSC and the "RDTSC exiting" VM-execution control was 1.                                                                                                                                                                                                                                                                                                                                                                                                      |
| 17                | <b>RSM.</b> Guest software attempted to execute RSM in SMM.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 18                | <b>VMCALL.</b> VMCALL was executed either by guest software (causing an ordinary VM exit) or by the executive monitor (causing an SMM VM exit; see Section 32.15.2).                                                                                                                                                                                                                                                                                                                                             |
| 19                | <b>VMCLEAR.</b> Guest software attempted to execute VMCLEAR.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 23                       | <b>VMREAD.</b> Guest software attempted to execute VMREAD.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 24                       | <b>VMRESUME.</b> Guest software attempted to execute VMRESUME.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 25                       | <b>VMWRITE.</b> Guest software attempted to execute VMWRITE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 26                       | <b>VMXOFF.</b> Guest software attempted to execute VMXOFF.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 27                       | <b>VMXON.</b> Guest software attempted to execute VMXON.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 28                       | <b>Control-register accesses.</b> Guest software attempted to access CR0, CR3, CR4, or CR8 using CLTS, LMSW, or MOV CR and the VM-execution control fields indicate that a VM exit should occur (see Section 26.1 for details). This basic exit reason is not used for trap-like VM exits following executions of the MOV to CR8 instruction when the “use TPR shadow” VM-execution control is 1. Such VM exits instead use basic exit reason 43.                                                                                                                             |
| 29                       | <b>MOV DR.</b> Guest software attempted a MOV to or from a debug register and the “MOV-DR exiting” VM-execution control was 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 30                       | <b>I/O instruction.</b> Guest software attempted to execute an I/O instruction and either:<br>1: The “use I/O bitmaps” VM-execution control was 0 and the “unconditional I/O exiting” VM-execution control was 1.<br>2: The “use I/O bitmaps” VM-execution control was 1 and a bit in the I/O bitmap associated with one of the ports accessed by the I/O instruction was 1.                                                                                                                                                                                                  |
| 31                       | <b>RDMSR.</b> Guest software attempted to execute RDMSR and either:<br>1: The “use MSR bitmaps” VM-execution control was 0.<br>2: The value of RCX is neither in the range 00000000H – 00001FFFH nor in the range C0000000H – C0001FFFH.<br>3: The value of RCX was in the range 00000000H – 00001FFFH and the $n^{\text{th}}$ bit in read bitmap for low MSRs is 1, where $n$ was the value of RCX.<br>4: The value of RCX is in the range C0000000H – C0001FFFH and the $n^{\text{th}}$ bit in read bitmap for high MSRs is 1, where $n$ is the value of RCX & 00001FFFH.   |
| 32                       | <b>WRMSR.</b> Guest software attempted to execute WRMSR and either:<br>1: The “use MSR bitmaps” VM-execution control was 0.<br>2: The value of RCX is neither in the range 00000000H – 00001FFFH nor in the range C0000000H – C0001FFFH.<br>3: The value of RCX was in the range 00000000H – 00001FFFH and the $n^{\text{th}}$ bit in write bitmap for low MSRs is 1, where $n$ was the value of RCX.<br>4: The value of RCX is in the range C0000000H – C0001FFFH and the $n^{\text{th}}$ bit in write bitmap for high MSRs is 1, where $n$ is the value of RCX & 00001FFFH. |
| 33                       | <b>VM-entry failure due to invalid guest state.</b> A VM entry failed one of the checks identified in Section 27.3.1.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 34                       | <b>VM-entry failure due to MSR loading.</b> A VM entry failed in an attempt to load MSRs. See Section 27.4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 36                       | <b>MWAIT.</b> Guest software attempted to execute MWAIT and the “MWAIT exiting” VM-execution control was 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 37                       | <b>Monitor trap flag.</b> A VM exit occurred due to the 1-setting of the “monitor trap flag” VM-execution control (see Section 26.5.2) or VM entry injected a pending MTF VM exit as part of VM entry (see Section 27.6.2).                                                                                                                                                                                                                                                                                                                                                   |
| 39                       | <b>MONITOR.</b> Guest software attempted to execute MONITOR and the “MONITOR exiting” VM-execution control was 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 40                       | <b>PAUSE.</b> Either guest software attempted to execute PAUSE and the “PAUSE exiting” VM-execution control was 1 or the “PAUSE-loop exiting” VM-execution control was 1 and guest software executed a PAUSE loop with execution time exceeding PLE_Window (see Section 26.1.3).                                                                                                                                                                                                                                                                                              |
| 41                       | <b>VM-entry failure due to machine-check event.</b> A machine-check event occurred during VM entry (see Section 27.9).                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 43                       | <b>TPR below threshold.</b> The logical processor determined that the value of bits 7:4 of the byte at offset 080H on the virtual-APIC page was below that of the TPR threshold VM-execution control field while the “use TPR shadow” VM-execution control was 1 either as part of TPR virtualization (Section 30.1.2) or VM entry (Section 27.7.7).                                                                                                                                                                                                                          |
| 44                       | <b>APIC access.</b> Guest software attempted to access memory at a physical address on the APIC-access page and the “virtualize APIC accesses” VM-execution control was 1 (see Section 30.4).                                                                                                                                                                                                                                                                                                                                                                                 |
| 45                       | <b>Virtualized EOI.</b> EOI virtualization was performed for a virtual interrupt whose vector indexed a bit set in the EOI-exit bitmap.                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Table C-1. Basic Exit Reasons (Contd.)**

| <b>Basic Exit Reason</b> | <b>Description</b>                                                                                                                                                                                                                                             |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 46                       | <b>Access to GDTR or IDTR.</b> Guest software attempted to execute LGDT, LIDT, SGDT, or SIDT and the “descriptor-table exiting” VM-execution control was 1.                                                                                                    |
| 47                       | <b>Access to LDTR or TR.</b> Guest software attempted to execute LLDT, LTR, SLDT, or STR and the “descriptor-table exiting” VM-execution control was 1.                                                                                                        |
| 48                       | <b>EPT violation.</b> An attempt to access memory with a guest-physical address was disallowed by the configuration of the EPT paging structures.                                                                                                              |
| 49                       | <b>EPT misconfiguration.</b> An attempt to access memory with a guest-physical address encountered a misconfigured EPT paging-structure entry.                                                                                                                 |
| 50                       | <b>INVEPT.</b> Guest software attempted to execute INVEPT.                                                                                                                                                                                                     |
| 51                       | <b>RDTSCP.</b> Guest software attempted to execute RDTSCP and the “enable RDTSCP” and “RDTSC exiting” VM-execution controls were both 1.                                                                                                                       |
| 52                       | <b>VMX-preemption timer expired.</b> The preemption timer counted down to zero.                                                                                                                                                                                |
| 53                       | <b>INVVPID.</b> Guest software attempted to execute INVVPID.                                                                                                                                                                                                   |
| 54                       | <b>WBINVD or WBNOINVD.</b> Guest software attempted to execute WBINVD or WBNOINVD and the “WBINVD exiting” VM-execution control was 1.                                                                                                                         |
| 55                       | <b>XSETBV.</b> Guest software attempted to execute XSETBV.                                                                                                                                                                                                     |
| 56                       | <b>APIC write.</b> Guest software completed a write to the virtual-APIC page that must be virtualized by VMM software (see Section 30.4.3.3).                                                                                                                  |
| 57                       | <b>RDRAND.</b> Guest software attempted to execute RDRAND and the “RDRAND exiting” VM-execution control was 1.                                                                                                                                                 |
| 58                       | <b>INVPCID.</b> Guest software attempted to execute INVPCID and the “enable INVPCID” and “INVLPG exiting” VM-execution controls were both 1.                                                                                                                   |
| 59                       | <b>VMFUNC.</b> Guest software invoked a VM function with the VMFUNC instruction and the VM function either was not enabled or generated a function-specific condition causing a VM exit.                                                                       |
| 60                       | <b>ENCLS.</b> Guest software attempted to execute ENCLS, “enable ENCLS exiting” VM-execution control was 1, and either (1) EAX < 63 and the corresponding bit in the ENCLS-exiting bitmap is 1; or (2) EAX ? 63 and bit 63 in the ENCLS-exiting bitmap is 1.   |
| 61                       | <b>RDSEED.</b> Guest software attempted to execute RDSEED and the “RDSEED exiting” VM-execution control was 1.                                                                                                                                                 |
| 62                       | <b>Page-modification log full.</b> The processor attempted to create a page-modification log entry and the value of the PML index was not in the range 0-511.                                                                                                  |
| 63                       | <b>XSAVES.</b> Guest software attempted to execute XSAVES, the “enable XSAVES/XRSTORS” was 1, and a bit was set in the logical-AND of the following three values: EDX:EAX, the IA32_XSS MSR, and the XSS-exiting bitmap.                                       |
| 64                       | <b>XRSTORS.</b> Guest software attempted to execute XRSTORS, the “enable XSAVES/XRSTORS” was 1, and a bit was set in the logical-AND of the following three values: EDX:EAX, the IA32_XSS MSR, and the XSS-exiting bitmap.                                     |
| 65                       | <b>PCONFIG.</b> Guest software attempted to execute PCONFIG, “enable PCONFIG” VM-execution control was 1, and either (1) EAX < 63 and the corresponding bit in the PCONFIG-exiting bitmap is 1; or (2) EAX ? 63 and bit 63 in the PCONFIG-exiting bitmap is 1. |
| 66                       | <b>SPP-related event.</b> The processor attempted to determine an access’s sub-page write permission and encountered an SPP miss or an SPP misconfiguration. See Section 29.3.4.2.                                                                             |
| 67                       | <b>UMWAIT.</b> Guest software attempted to execute UMWAIT and the “enable user wait and pause” and “RDTSC exiting” VM-execution controls were both 1.                                                                                                          |
| 68                       | <b>TPAUSE.</b> Guest software attempted to execute TPAUSE and the “enable user wait and pause” and “RDTSC exiting” VM-execution controls were both 1.                                                                                                          |
| 69                       | <b>LOADIWKEY.</b> Guest software attempted to execute LOADIWKEY and the “LOADIWKEY exiting” VM-execution control was 1.                                                                                                                                        |

**Table C-1. Basic Exit Reasons (Contd.)**

| <b>Basic Exit Reason</b> | <b>Description</b>                                                                                                                                                                                                                                               |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 70                       | <b>ENCLV.</b> Guest software attempted to execute ENCLV, the “enable ENCLV exiting” VM-execution control was 1, and either (1) EAX < 63 and the corresponding bit in the ENCLV-exiting bitmap is 1; or (2) EAX ? 63 and bit 63 in the ENCLV-exiting bitmap is 1. |
| 72                       | <b>ENQCMD PASID translation failure.</b> A VM exit occurred during PASID translation because the present bit was clear in a PASID-directory entry, the valid bit was clear in a PASID-table entry, or one of the entries set a reserved bit.                     |
| 73                       | <b>ENQCMDS PASID translation failure.</b> A VM exit occurred during PASID translation because the present bit was clear in a PASID-directory entry, the valid bit was clear in a PASID-table entry, or one of the entries set a reserved bit.                    |
| 74                       | <b>Bus lock.</b> The processor asserted a bus lock while the “bus-lock detection” VM-execution control was 1. (Such VM exits will also set bit 26 of the exit-reason field.)                                                                                     |
| 75                       | <b>Instruction timeout.</b> The “instruction timeout” VM-execution control was 1 and certain operations prevented the processor from reaching an instruction boundary within the amount of time specified by the instruction-timeout control.                    |

Automatic thermal monitoring mechanism, 15-36

### B

B (busy) flag  
    TSS descriptor, 8-5, 8-11, 8-16  
B (default stack size) flag  
    segment descriptor, 22-1, 23-33  
B0-B3 (BP condition detected) flags  
    DR6 register, 18-4  
Backlink (see Previous task link)  
Base address fields, segment descriptor, 3-10  
BD (debug register access detected) flag, DR6 register, 18-11  
Binary numbers, 1-8  
BINIT# signal, 2-26  
BIOS role in microcode updates, 10-38  
Bit order, 1-7  
BOUND instruction, 2-5, 6-4, 6-30  
BOUND range exceeded exception (#BR), 6-30  
BPO#, BP1#, BP2#, and BP3# pins, 18-39, 18-41  
Branch record  
    branch trace message, 18-15  
    IA-32e mode, 18-23  
    saving, 18-17, 18-27, 18-28, 18-36  
    saving as a branch trace message, 18-15  
    structure, 18-37  
    structure of in BTS buffer, 18-21  
Branch trace message (see BTM)  
Branch trace store (see BTS)  
Breakpoint exception (#BP), 6-4, 6-28, 18-11  
Breakpoints  
    data breakpoint, 18-6  
    data breakpoint exception conditions, 18-10  
    description of, 18-1  
    DR0-DR3 debug registers, 18-4  
    example, 18-6  
    exception, 6-28  
    field recognition, 18-6, 18-7  
    general-detect exception condition, 18-10  
    instruction breakpoint, 18-6  
    instruction breakpoint exception condition, 18-9  
    I/O breakpoint exception conditions, 18-10  
    LENO - LEN3 (Length) fields  
        DR7 register, 18-6  
    R/W0-R/W3 (read/write) fields  
        DR7 register, 18-5  
    single-step exception condition, 18-11  
    task-switch exception condition, 18-11  
BS (single step) flag, DR6 register, 18-4  
BSP flag, IA32\_APIC\_BASE MSR, 11-8  
BSWAP instruction, 23-4  
BT (task switch) flag, DR6 register, 18-4, 18-11  
BTC instruction, 9-4  
BTF (single-step on branches) flag  
    DEBUGCTLMSR MSR, 18-41  
BTMs (branch trace messages)  
    description of, 18-15  
    enabling, 18-13, 18-25, 18-26, 18-36, 18-38, 18-39  
    TR (trace message enable) flag  
        MSR\_DEBUGCTLA MSR, 18-36  
        MSR\_DEBUGCTLB MSR, 18-13, 18-38, 18-39  
BTR instruction, 9-4

BTS buffer  
    description of, 18-20  
    introduction to, 18-12, 18-15  
    records in, 18-21  
    setting up, 18-25  
    structure of, 18-21, 18-23, 20-21  
BTS instruction, 9-4  
BTS (branch trace store) facilities  
    availability of, 18-35  
    BTS\_UNAVAILABLE flag,  
        IA32\_MISC\_ENABLE MSR, 18-20  
    introduction to, 18-12  
    setting up BTS buffer, 18-25  
    writing an interrupt service routine for, 18-26  
BTS\_UNAVAILABLE, 18-20  
Built-in self-test (BIST)  
    description of, 10-1  
    performing, 10-5  
Bus  
    errors detected with MCA, 16-27  
    hold, 23-35  
    locking, 9-3, 23-35  
Byte order, 1-7

### C

C (conforming) flag, segment descriptor, 5-11  
C1 flag, x87 FPU status word, 23-8, 23-14  
C2 flag, x87 FPU status word, 23-8  
Cache control, 12-20  
    adaptive mode, L1 Data Cache, 12-18  
    cache management instructions, 12-17, 12-18  
    cache mechanisms in IA-32 processors, 23-30  
    caching terminology, 12-5  
    CD flag, CR0 control register, 12-10, 23-19  
    choosing a memory type, 12-8  
    CPUID feature flag, 12-18  
    flags and fields, 12-10  
    flushing TLBs, 12-19  
    G (global) flag  
        page-directory entries, 12-13  
        page-table entries, 12-13  
    internal caches, 12-1  
    MemTypeGet() function, 12-29  
    MemTypeSet() function, 12-31  
    MESI protocol, 12-5, 12-9  
    methods of caching available, 12-6  
    MTRR initialization, 12-29  
    MTRR precedences, 12-28  
    MTRRs, description of, 12-20  
    multiple-processor considerations, 12-32  
    NW flag, CR0 control register, 12-13, 23-19  
    operating modes, 12-12  
    overview of, 12-1  
    page attribute table (PAT), 12-33  
    PCD flag  
        CR3 control register, 12-13  
        page-directory entries, 12-13, 12-33  
        page-table entries, 12-13, 12-33  
    PGE (page global enable) flag, CR4 control register, 12-13  
    precedence of controls, 12-13  
    preventing caching, 12-16  
    protocol, 12-9  
    PWT flag  
        CR3 control register, 12-13  
        page-directory entries, 12-33

page-table entries, 12-33  
 remapping memory types, 12-29  
 setting up memory ranges with MTRRs, 12-22  
 shared mode, L1 Data Cache, 12-18  
 variable-range MTRRs, 12-23, 12-25  
**Caches**, 2-7  
 cache hit, 12-5  
 cache line, 12-5  
 cache line fill, 12-5  
 cache write hit, 12-5  
 description of, 12-1  
 effects of a locked operation on internal processor caches, 9-6  
 enabling, 10-7  
 management, instructions, 2-25, 12-17  
**Caching**  
 cache control protocol, 12-9  
 cache line, 12-5  
 cache management instructions, 12-17  
 cache mechanisms in IA-32 processors, 23-30  
 caching terminology, 12-5  
 choosing a memory type, 12-8  
 flushing TLBs, 12-19  
 implicit caching, 12-19  
 internal caches, 12-1  
 L1 (level 1) cache, 12-4  
 L2 (level 2) cache, 12-4  
 L3 (level 3) cache, 12-4  
 methods of caching available, 12-6  
 MTRRs, description of, 12-20  
 operating modes, 12-12  
 overview of, 12-1  
 self-modifying code, effect on, 12-18, 23-30  
 snooping, 12-6  
 store buffer, 12-20  
 TLBs, 12-5  
 UC (strong uncacheable) memory type, 12-6  
 UC- (uncacheable) memory type, 12-6  
 WB (write back) memory type, 12-7  
 WC (write combining) memory type, 12-7  
 WP (write protected) memory type, 12-7  
 write-back caching, 12-6  
 WT (write through) memory type, 12-7  
**Call gates**  
 16-bit, interlevel return from, 23-33  
 accessing a code segment through, 5-15  
 description of, 5-13  
 for 16-bit and 32-bit code modules, 22-1  
 IA-32e mode, 5-14  
 introduction to, 2-4  
 mechanism, 5-15  
 privilege level checking rules, 5-16  
**CALL instruction**, 2-5, 3-8, 5-10, 5-15, 5-20, 8-2, 8-9, 8-11, 22-5  
**Caller access privileges**, checking, 5-26  
**Calls**  
 16 and 32-bit code segments, 22-3  
 controlling operand-size attribute, 22-5  
 returning from, 5-20  
**Catastrophic shutdown detector**  
 Thermal monitoring  
     catastrophic shutdown detector, 15-37  
 catastrophic shutdown detector, 15-36  
**CC0 and CC1 (counter control) fields, CESR MSR (Pentium processor)**, 20-137  
**CD (cache disable) flag, CRO control register**, 2-15, 10-7, 12-10, 12-12, 12-13, 12-16, 12-32, 23-18, 23-19, 23-30  
**CESR (control and event select) MSR (Pentium processor)**, 20-136, 20-137  
**CLFLSH feature flag, CPUID instruction**, 10-8  
**CLFLUSH instruction**, 2-16, 10-8, 12-17  
**CLI instruction**, 6-7  
**Clocks**  
 counting processor clocks, 20-138  
 Hyper-Threading Technology, 20-138  
 nominal CPI, 20-138  
 non-halted clockticks, 20-138  
 non-halted CPI, 20-138  
 non-sleep Clockticks, 20-138  
 time stamp counter, 20-138  
**CLTS instruction**, 2-24, 5-24, 26-2, 26-7  
**Cluster model, local APIC**, 11-24  
**CMOVcc instructions**, 23-4  
**CMPXCHG instruction**, 9-4, 23-4  
**CMPXCHG8B instruction**, 9-4, 23-5  
**Code modules**  
 16 bit vs. 32 bit, 22-1  
 mixing 16-bit and 32-bit code, 22-1

## INDEX

### O

Obsolete instructions, 23-5, 23-15

OF flag, EFLAGS register, 6-29

On-die digital thermal sensor, 15-42

  relevant MSRs, 15-42

  sensor enumeration, 15-42

On-Demand

  clock modulation enable bits, 15-40

On-demand

  clock modulation duty cycle bits, 15-40

On-die sensors, 15-36

Opcodes

  undefined, 23-5

Operands

  instruction, 1-8

  operand-size prefix, 22-1

Operating modes

  64-bit mode, 2-7

  compatibility mode, 2-7

  IA-32e mode, 2-7, 2-8

  introduction to, 2-7

  protected mode, 2-7

  SMM (system management mode), 2-7

  transitions between, 2-8

  virtual-8086 mode, 2-8

VMX operation

  enabling and entering, 24-3

OR instruction, 9-4

OS (operating system) flag

  PerfEvtSel0 and PerfEvtSel1 MSRs (P6 only), 20-4, 20-134

OSFXSR (FXSAVE/FXRSTOR support) flag

  CR4 control register, 2-18, 10-8, 14-2

OSXMMEXCPT (SIMD floating-point exception support) flag, CR4

  control register, 2-18, 6-53, 10-8, 14-3

OUT instruction, 9-16, 26-2

Out-of-spec status bit, 15-43, 15-46

Out-of-spec status log, 15-43, 15-46

OUTS/OUTSB/OUTSW/OUTSD instruction, 18-10, 26-2

Overflow exception (#OF), 6-29

Overheat interrupt enable bit, 15-44, 15-47

### P

P (present) flag

  page-directory entry, 6-44

  page-table entry, 6-44

  segment descriptor, 3-11

P5\_MC\_ADDR MSR, 16-13, 16-29

P5\_MC\_TYPE MSR, 16-13, 16-29

P6 family processors

  compatibility with FP software, 23-7

  description of, 1-1

  last branch, interrupt, and exception recording, 18-40

PAE paging

  feature flag, CR4 register, 2-18, 2-19

  flag, CR4 control register, 3-6, 23-18, 23-19

Page attribute table (PAT)

  compatibility with earlier IA-32 processors, 12-36

  detecting support for, 12-34

  IA32\_PAT MSR, 12-34

  introduction to, 12-33

  memory types that can be encoded with, 12-34

  MSR, 12-13

  precedence of cache controls, 12-14

  programming, 12-35

selecting a memory type with, 12-35

Page directories, 2-6

Page directory

  base address (PDBR), 8-5

  introduction to, 2-6

  overview, 3-2

  setting up during initialization, 10-10

Page directory pointers, 2-6

Page frame (see Page)

Page tables, 2-6

  introduction to, 2-6

  overview, 3-2

  setting up during initialization, 10-10

Page-directory entries, 12-5

Page-fault exception (#PF), 4-54, 6-44, 23-21

Pages

  disabling protection of, 5-1

  enabling protection of, 5-1

  introduction to, 2-6

  overview, 3-2

  PG flag, CRO control register, 5-1

  split, 23-15

Page-table entries, 12-5, 12-19

Paging

  combining segment and page-level protection, 5-29

  combining with segmentation, 3-5

  defined, 3-1

  IA-32e mode, 2-6

  initializing, 10-10

  introduction to, 2-6

  large page size MTRR considerations, 12-33

  mapping segments to pages, 4-54

  page-fault exception, 6-44, 6-55, 6-56

  page-level protection, 5-2, 5-3, 5-27

  page-level protection flags, 5-28

  virtual-8086 tasks, 21-7

Parameter

  passing, between 16- and 32-bit call gates, 22-6

  translation, between 16- and 32-bit code segments, 22-6

PAUSE instruction, 2-16, 26-3

PBi (performance monitoring/breakpoint pins) flags,

  DEBUGCTLMSR MSR, 18-39, 18-41

PC (pin control) flag, PerfEvtSel0 and PerfEvtSel1 MSRs (P6 family processors), 20-4, 20-135

PC0 and PC1 (pin control) fields, CESR MSR (Pentium processor), 20-137

PCD pin (Pentium processor), 12-13

PCD (page-level cache disable) flag

  CR3 control register, 2-17, 12-13, 23-18, 23-30

  page-directory entries, 10-7, 12-13, 12-33

  page-table entries, 10-7, 12-13, 12-33, 23-31

PCE (performance monitoring counter enable) flag, CR4 control register, 2-18, 5-24, 20-109, 20-135

PCE (performance-monitoring counter enable) flag, CR4 control register, 23-18

PDBR (see CR3 control register)

PE (protection enable) flag, CRO control register, 2-17, 5-1, 10-10, 10-13, 32-9

PEBS records, 18-23

PEBS (precise event-based sampling) facilities

  availability of, 20-119

  description of, 20-107, 20-119

  DS save area, 18-19

  IA-32e mode, 18-23

  PEBS buffer, 18-20, 20-119

PEBS records, 18-19, 18-22  
writing a PEBS interrupt service routine, 20-120  
writing interrupt service routine, 18-26

**PEBS\_UNAVAILABLE flag**  
IA32\_MISC\_ENABLE MSR, 18-20

Pentium 4 processor, 1-1  
compatibility with FP software, 23-7  
last branch, interrupt, and exception recording, 18-35  
time-stamp counter, 18-42

Pentium II processor, 1-3

Pentium III processor, 1-3

Pentium M processor  
last branch, interrupt, and exception recording, 18-39  
time-stamp counter, 18-42

Pentium Pro processor, 1-3

Pentium processor, 1-1, 23-7  
compatibility with MCA, 16-1  
performance-monitoring counters, 20-136

PerfCtr0 and PerfCtr1 MSRs  
(P6 family processors), 20-134, 20-135

PerfEvtSel0 and PerfEvtSel1 MSRs  
(P6 family processors), 20-134

PerfEvtSel0 and PerfEvtSel1 MSRs (P6 family processors), 20-134

**Performance events**  
architectural, 20-1  
Intel Core Solo and Intel Core Duo processors, 20-1  
non-architectural, 20-1  
Pentium 4 and Intel Xeon processors, 18-35  
Pentium M processors, 18-39

Performance state, 15-1

**Performance-monitoring counters**  
counted events (Pentium processors), 20-138  
description of, 20-1, 20-2  
interrupt, 11-1  
introduction of in IA-32 processors, 23-37  
monitoring counter overflow (P6 family processors), 20-136  
overflow, monitoring (P6 family processors), 20-136  
overview of, 2-7

P6 family processors, 20-133

Pentium II processor, 20-133

Pentium Pro processor, 20-133

Pentium processor, 20-136  
reading, 2-26, 20-135  
setting up (P6 family processors), 20-134  
software drivers for, 20-135  
starting and stopping, 20-135

**PG (paging) flag**  
CRO control register, 2-15, 5-1

**PG (paging) flag, CRO control register**, 10-10, 10-13, 23-32, 32-9

**PGE (page global enable) flag, CR4 control register**, 2-18, 12-13, 23-18, 23-19

PhysBase field, IA32\_MTRR\_PHYSBASEn MTRR, 12-24, 12-26

**Physical address extension**  
introduction to, 3-6

**Physical address space**  
4 GBytes, 3-6  
64 GBytes, 3-6  
addressing, 2-6  
defined, 3-1  
description of, 3-6  
IA-32e mode, 3-6  
mapped to a task, 8-17  
mapping with variable-range MTRRs, 12-23, 12-25

Physical destination mode, local APIC, 11-23

**PhysMask**

IA32\_MTRR\_PHYSMASKn MTRR, 12-24, 12-26  
PM0/BPO and PM1/BP1 (performance-monitor) pins (Pentium processor), 20-136, 20-137, 20-138

**PML4 tables**, 2-6

**Pointers**  
code-segment pointer size, 22-4  
limit checking, 5-25  
validation, 5-24

**POP instruction**, 3-8

**POPF instruction**, 6-7, 18-11

**Power consumption**  
software controlled clock, 15-36, 15-40

**Precise event-based sampling (see PEBS)**

**PREFETCHh instruction**, 2-16, 12-17

**Previous task link field, TSS**, 8-5, 8-15, 8-16

**Privilege levels**  
checking when accessing data segments, 5-8  
checking, for call gates, 5-15  
checking, when transferring program control between code segments, 5-10  
description of, 5-6  
protection rings, 5-8

**Privileged instructions**, 5-23

**Processor families**  
06H, 17-1  
0FH, 17-1

**Processor management**  
initialization, 10-1  
local APIC, 11-1  
microcode update facilities, 10-27  
overview of, 9-1  
See also: multiple-processor management

**Processor ordering**, description of, 9-6

**PROCHOT# log**, 15-43, 15-46

**PROCHOT# or FORCEPR# event bit**, 15-42, 15-46

**Protected mode**  
IDT initialization, 10-10  
initialization for, 10-9  
mixing 16-bit and 32-bit code modules, 22-1  
mode switching, 10-13  
PE flag, CRO register, 5-1  
switching to, 5-1, 10-13  
system data structures required during initialization, 10-9

**Protection**  
combining segment & page-level, 5-29  
disabling, 5-1  
enabling, 5-1  
flags used for page-level protection, 5-2, 5-3  
flags used for segment-level protection, 5-2  
IA-32e mode, 5-3  
of exception, interrupt-handler procedures, 6-16  
overview of, 5-1  
page level, 5-1, 5-27, 5-28, 5-30  
page level, overriding, 5-29  
page-level protection flags, 5-28  
read/write, page level, 5-28  
segment level, 5-1  
user/supervisor type, 5-28

**Protection rings**, 5-8

**PSE (page size extension) flag**  
CR4 control register, 2-17, 12-20, 23-18, 23-19

**PSE-36 page size extension**, 3-6

**Pseudo-functions**  
VMfail, 31-2  
VMfailInvalid, 31-2

## INDEX

## INDEX

introduction of into the IA-32 architecture, 23-3  
providing exception handlers for, 14-4, 14-5  
providing operating system support for, 14-1  
saving and restoring state, 14-6  
saving state on task, context switches, 14-6  
SIMD Floating-point exception (#XM), 6-53  
using TS flag to control saving state, 14-7

SSE2 feature flag  
CPUID instruction, 14-2

SSE3 extensions  
checking for with CPUID, 14-2  
CPUID feature flag, 10-8  
EM flag, 2-16  
emulation of, 14-6  
example verifying SS3 support, 9-46, 9-49, 15-2  
facilities for automatic saving of state, 14-6, 14-7  
initialization, 10-8  
introduction of into the IA-32 architecture, 23-3  
providing exception handlers for, 14-4, 14-5  
providing operating system support for, 14-1  
saving and restoring state, 14-6  
saving state on task, context switches, 14-6  
using TS flag to control saving of state, 14-7

SSE3 feature flag  
CPUID instruction, 14-2

Stack fault exception (#SS), 6-40

Stack fault, x87 FPU, 23-8, 23-13

Stack pointers  
privilege level 0, 1, and 2 stacks, 8-5  
size of, 3-11

Stack segments  
paging of, 2-6  
privilege level check when loading SS register, 5-10  
size of stack pointer, 3-11

Stack switching  
exceptions/interrupts when switching stacks, 6-8  
IA-32e mode, 6-21  
inter-privilege level calls, 5-17

Stack-fault exception (#SS), 23-34

Stacks  
error code pushes, 23-32  
faults, 6-40  
for privilege levels 0, 1, and 2, 5-17  
interlevel RET/IRET  
from a 16-bit interrupt or call gate, 23-33  
interrupt stack table, 64-bit mode, 6-22  
management of control transfers for  
16- and 32-bit procedure calls, 22-4  
operation on pushes and pops, 23-32  
pointers to in TSS, 8-5  
stack switching, 5-17, 6-21  
usage on call to exception  
or interrupt handler, 23-33

Stepping information, following processor initialization or reset, 10-5

STI instruction, 6-7

Store buffer  
caching terminology, 12-5  
characteristics of, 12-4  
description of, 12-5, 12-20  
in IA-32 processors, 23-34  
location of, 12-1  
operation of, 12-20

STPCLK# pin, 6-3

STR instruction, 2-24, 3-16, 8-7

Strong uncached (UC) memory type  
description of, 12-6  
effect on memory ordering, 9-17  
use of, 10-8, 12-8

Sub C-state, 15-35

SUB instruction, 9-4

Supervisor mode  
description of, 5-28  
U/S (user/supervisor) flag, 5-28

SVR (spurious-interrupt vector register), local APIC, 11-8, 23-28

SWAPGS instruction, 2-7

SYSCALL instruction, 2-7, 5-22

SYSENTER instruction, 3-8, 5-10, 5-20, 5-21

SYSENTER\_CS\_MSR, 5-21

SYSENTER\_EIP\_MSR, 5-21

SYSENTER\_ESP\_MSR, 5-21

SYSEXIT instruction, 3-8, 5-10, 5-20, 5-21

SYSRET instruction, 2-7, 5-22

System  
architecture, 2-1, 2-2  
data structures, 2-2  
instructions, 2-7, 2-23  
registers in IA-32e mode, 2-7  
registers, introduction to, 2-6  
segment descriptor, layout of, 5-2  
segments, paging of, 2-6

System programming  
MMX technology, 13-1

System-management mode (see SMM)

**T**

T (debug trap) flag, TSS, 8-5

Task gates  
descriptor, 8-8  
executing a task, 8-2  
handling a virtual-8086 mode interrupt or exception through, 21-14  
IA-32e mode, 2-5  
in IDT, 6-10  
introduction for IA-32e, 2-4  
introduction to, 2-4, 2-5  
layout of, 6-10  
referencing of TSS descriptor, 6-17

Task management, 8-1  
data structures, 8-3  
mechanism, description of, 8-2

Task register, 3-16  
description of, 2-13, 8-1, 8-7  
IA-32e mode, 2-13  
initializing, 10-11  
introduction to, 2-6

Task switching  
description of, 8-3  
exception condition, 18-11  
operation, 8-10  
preventing recursive task switching, 8-16  
saving MMX state on, 13-4  
saving SSE/SSE2/SSE3 state  
on task or context switches, 14-6

T (debug trap) flag, 8-5

Tasks  
address space, 8-16  
description of, 8-1  
exception-handler task, 6-11

executing, 8-2  
 Intel 286 processor tasks, 23-37  
 interrupt-handler task, 6-11  
 interrupts and exceptions, 6-17  
 linking, 8-15  
 logical address space, 8-18  
 management, 8-1  
 mapping linear and physical address space, 8-17  
 restart following an exception or interrupt, 6-5  
 state (context), 8-2, 8-3  
 structure, 8-1  
 switching, 8-3  
 task management data structures, 8-3

**Threshold #1 interrupt enable bit**, 15-44, 15-47  
**Threshold #1 value**, 15-44, 15-47  
**Threshold #2 interrupt enable**, 15-44, 15-47  
**Threshold #2 value**, 15-44, 15-47  
**TI (table indicator) flag, segment selector**, 3-7  
**Timer, local APIC**, 11-16  
**Time-stamp counter**  
 counting clockticks, 20-139  
 description of, 18-42  
**IA32\_TIME\_STAMP\_COUNTER MSR**, 18-42  
**RDTSC instruction**, 18-42  
 reading, 2-26  
 software drivers for, 20-135  
**TSC flag**, 18-42  
**TSD flag**, 18-42  
**TLBs**  
 description of, 12-1, 12-5  
 flushing, 12-19  
 invalidating (flushing), 2-25  
 relationship to PGE flag, 23-19  
 relationship to PSE flag, 12-20  
**TM1 and TM2**  
 See: thermal monitoring, 15-37  
**TMR**  
 Trigger Mode Register, 11-31, 11-39, 11-41, 11-47  
**TMR (Trigger Mode Register), local APIC**, 11-30  
**TPR**  
 Task Priority Register, 11-38, 11-41  
**TR (trace message enable) flag**  
 DEBUGCTLMSR MSR, 18-13, 18-36, 18-38, 18-39, 18-41  
**Trace cache**, 12-4, 12-5  
**Transcendental instruction accuracy**, 23-8, 23-14  
**Translation lookaside buffer (see TLB)**  
**Trap gates**  
 difference between interrupt and trap gates, 6-17  
 for 16-bit and 32-bit code modules, 22-1  
 handling a virtual-8086 mode interrupt or exception through, 21-12  
 in IDT, 6-10  
 introduction for IA-32e, 2-4  
 introduction to, 2-4, 2-5  
 layout of, 6-10  
**Traps**  
 description of, 6-5  
 restarting a program or task after, 6-5  
**TS (task switched) flag**  
 CR0 control register, 2-15, 2-24, 6-32, 13-1, 14-3, 14-7  
**TSD (time-stamp counter disable) flag**  
 CR4 control register, 2-17, 5-24, 18-43, 23-18  
**TSS**  
 16-bit TSS, structure of, 8-18  
 32-bit TSS, structure of, 8-3  
 64-bit mode, 8-19  
 CR3 control register (PDBR), 8-4, 8-17  
 description of, 2-4, 2-5, 8-1, 8-3  
 EFLAGS register, 8-4  
 EFLAGS.NT, 8-15  
 EIP, 8-5  
 executing a task, 8-2  
 floating-point save area, 23-12  
 format in 64-bit mode, 8-19  
 general-purpose registers, 8-4  
 IA-32e mode, 2-5  
 initialization for multitasking, 10-10  
 interrupt stack table, 8-19  
 invalid TSS exception, 6-36  
 IRET instruction, 8-15  
 I/O map base address field, 8-5, 23-29  
 I/O permission bit map, 8-5, 8-19  
 LDT segment selector field, 8-5, 8-16  
 link field, 6-17  
 order of reads/writes to, 23-29  
 pointed to by task-gate descriptor, 8-8  
 previous task link field, 8-5, 8-15, 8-16  
 privilege-level 0, 1, and 2 stacks, 5-17  
 referenced by task gate, 6-17  
 segment registers, 8-4  
**T (debug trap) flag**, 8-5  
**task register**, 8-7
